Abstract

A distributed single-hop wireless network with K links is considered, where the links are partitioned into a fixed number (M) of clusters each operating in a subchannel with bandwidth $\frac{W}{M}$. The subchannels are assumed to be orthogonal to each other. A general shadow-fading model, described by parameters (α, ϖ), is considered where α denotes the probability of shadowing and ϖ ($\varpi \leq 1$) represents the average cross-link gains. The main goal of this paper is to find the maximum network throughput in the asymptotic regime of $K \to \infty$, which is achieved by: i) proposing a distributed and non-iterative power allocation strategy, where the objective of each user is to maximize its best estimate (based on its local information, i.e., direct channel gain) of the average network throughput, and ii) choosing the optimum value for M. In the first part of the paper, the network throughput is defined as the *average sum-rate* of the network, which is shown to scale as $\Theta(\log K)$. Moreover, it is proved that in the strong interference scenario, the optimum power allocation strategy for each user is a threshold-based on-off scheme. In the second part, the network throughput is defined as the *guaranteed sum-rate*, when the outage probability approaches zero. In this scenario, it is demonstrated that the on-off power allocation scheme maximizes the throughput, which scales as $\frac{W}{\alpha\varpi} \log K$. Moreover, the optimum spectrum sharing for maximizing the average sum-rate and the guaranteed sum-rate is achieved at $M = 1$.

I. INTRODUCTION

A. History

A primary challenge in wireless networks is to use available resources efficiently so that the network throughput is maximized. Throughput maximization in multi-user wireless networks has been addressed from different perspectives; resource allocation [3]–[5], scheduling [6], routing by using relay nodes [7], exploiting mobility of the nodes [8] and exploiting channel characteristics (e.g., power decay-versus-distance law [9]–[11], geometric pathloss and fading [12]–[14]).

Among different resource allocation strategies, power and spectrum allocation have long been regarded as efficient tools to mitigate the interference and improve the network throughput. In recent years, power and spectrum allocation schemes have been extensively studied in cellular and multihop wireless networks [3], [4], [15]–[20]. In [19], the authors provide a comprehensive survey in the area of resource allocation, in particular in the context of spectrum assignment. Much of these works rely on centralized and cooperative algorithms. Clearly, centralized resource allocation schemes provide a significant improvement in the network throughput over decentralized (distributed) approaches. However, they require extensive knowledge of the network configuration. In particular, when the number of nodes is large, deploying such centralized schemes may not be practically feasible. Due to significant challenges in using centralized approaches, the attention of the researchers has been drawn to the decentralized resource allocation schemes [21]–[26].

In decentralized schemes, the decisions concerning network parameters (e.g., rate and/or power) are made by the individual nodes based on their local information. The local decision parameters that can be used for adjusting the rate are the Signal-to-Interference-plus-Noise Ratio (SINR) and the direct channel gain. Most of the works on decentralized throughput maximization target the SINR parameter by using iterative algorithms [23]–[25]. This leads to the use of game theory concepts [27] where the main challenge is the convergence issue. For instance, Etkin *et al.* [25] develop power and spectrum allocation strategies by using game theory. Under the assumptions of the omniscient nodes and strong interference, the authors show that Frequency-Division Multiplexing (FDM) is the optimal scheme in the sense of throughput maximization. They use an iterative algorithm that converges to the optimum power values. In [24], Huang *et al.* propose an iterative power control algorithm in an ad hoc wireless network, in which receivers broadcast adjacent channel gains and interference prices to optimize the network throughput. However, this algorithm incurs a great amount of overhead in large wireless networks.

A more practical approach is to rely on the channel gains as local decision parameters and avoid iterative schemes. Motivated by this consideration, we study the throughput maximization of a distributed wireless network with K links, operating in a bandwidth of W. To mitigate the interference, the links are partitioned into a fixed number (M) of clusters, each operating in a subchannel with bandwidth $\frac{W}{M}$, where the subchannels are orthogonal to each other. Throughput maximization of the underlying network is achieved by proposing a distributed and non-iterative power allocation strategy based on the direct channel gains, and then choosing the optimum value for M.

B. Contributions and Relations to Previous Works

In this paper, we study the throughput maximization of a spatially distributed wireless network with K links, where the sources and their corresponding destinations communicate directly with each other without using relay nodes. Wireless networks using unlicensed spectrum (e.g. Wi-Fi systems based on IEEE 802.11b standard [28]) are a typical example of such networks. The cross-link channel gains are assumed to be Rayleigh-distributed with shadow-fading, described by parameters (α, ϖ), where α denotes the probability of shadowing and ϖ ($\varpi \leq 1$) represents the statistical average of the Rayleigh distribution.

The above configuration differs from the geometric models proposed in [8]–[11], [29], in which the signal power decays based on the distance between nodes. Unlike [22]–[25] which relies on an iterative algorithm using SINR, we assume that each transmitter adjusts its power solely based on its direct channel gain.

If each user maximizes its rate selfishly, the optimum power allocation strategy for all users is to transmit with full power. This strategy results in excessive interference, degrading the average network throughput. To prevent this undesirable effect, one should consider the negative impact of each user's power on other links. A reasonable approach for each user is to choose a non-iterative power allocation strategy to maximize its best local estimate of the network throughput.

The network throughput in this paper is defined in two ways: i) *average sum-rate* and ii) *guaranteed sum-rate*. It is established that the average sum-rate in the network scales at most as $\Theta(\log K)$ in the asymptotic case of $K \to \infty$. This order is achievable by the distributed *threshold-based on-off scheme* (i.e., links with a direct channel gain above certain threshold transmit at full power and the rest remain silent). Moreover, in the strong interference scenario, the on-off power allocation scheme is the optimal strategy. In addition, the on-off power allocation scheme is always optimal for maximizing the guaranteed sum-rate in the network, which is shown to scale as $\frac{W}{\alpha\varpi} \log K$. These results are different from the result of [30] where the authors use a similar on-off scheme for $M = 1$ and prove its optimality only among all *on-off schemes*. This work also differs from [31] and [32] in terms of the network model. We use a distributed power allocation strategy in a single-hop network, while [31] and [32] consider an ad hoc network model with random connections and relay nodes.

We optimize the average network throughput in terms of the number of the clusters, M. It is proved that the maximum average sum-rate and the guaranteed sum-rate of the network for every value of α and

ϖ is achieved at $M = 1$. In other words, splitting the bandwidth W into M orthogonal sub-channels does not increase the throughput.

The rest of the paper is organized as follows. In Section II, the network model and objectives are described. The distributed on-off power allocation strategy and the network average sum-rate are presented in Section III. We analyze the network guaranteed sum-rate in Section IV. Finally, in Section V, an overview of the results and some conclusion remarks are presented.

C. Notations

For any functions $f(n)$ and $g(n)$ [33]:

- $f(n) = O(g(n))$ means that $\lim_{n\to\infty} \left|\frac{f(n)}{g(n)}\right| < \infty$.
- $f(n) = o(g(n))$ means that $\lim_{n\to\infty} \left|\frac{f(n)}{g(n)}\right| = 0$.
- $f(n) = \omega(g(n))$ means that $\lim_{n\to\infty} \frac{f(n)}{g(n)} = \infty$.
- $f(n) = \Omega(g(n))$ means that $\lim_{n\to\infty} \frac{f(n)}{g(n)} > 0$.
- $f(n) = \Theta(g(n))$ means that $\lim_{n\to\infty} \frac{f(n)}{g(n)} = c$, where $0 < c < \infty$.
- $f(n) \sim g(n)$ means that $\lim_{n\to\infty} \frac{f(n)}{g(n)} = 1$.
- $f(n) \lesssim g(n)$ means that $\lim_{n\to\infty} \frac{f(n)}{g(n)} \leq 1$.
- $f(n) \approx g(n)$ means that $f(n)$ is approximately equal to $g(n)$, i.e., if we replace $f(n)$ by $g(n)$ in the equations, the results still hold.

Throughout the paper, we use $\log(.)$ as the natural logarithm function and $\mathbb{P}\{.\}$ denotes the probability of the given event. Boldface letters denote vectors; and for a random variable x, $\bar{x}$ means $\mathbb{E}[x]$, where $\mathbb{E}[.]$ represents the expectation operator. RH(.) represents the right hand side of the equations.

II. NETWORK MODEL AND OBJECTIVES

A. Network Model

In this work, we consider a single-hop wireless network consisting of K pairs of nodes[1] indexed by $\{1, ..., K\}$, operating in bandwidth W. All the nodes in the network are assumed to have a single antenna. The links are assumed to be randomly divided into M clusters denoted by $\mathbb{C}_j$, $j = 1, ..., M$ such that the number of links in all clusters are the same. Without loss of generality, we assume that $\mathbb{C}_j \triangleq \{(j-1)n+1, ..., jn\}$, where $n \triangleq \frac{K}{M}$ denotes the cardinality of the set $\mathbb{C}_j$ which is assumed to be known to all users[2]. To eliminate the mutual interference among the clusters, we assume an M-dimensional orthogonal coordinate system in which the bandwidth W is split into M disjoint subchannels each with bandwidth $\frac{W}{M}$. It is assumed that the links in $\mathbb{C}_j$ operate in subchannel j. We also assume that M is fixed, i.e., it does not scale with K. The power of Additive White Gaussian Noise (AWGN) at each receiver is $\frac{N_0 W}{M}$, where N_0 is the noise power spectral density.

---

[1] The term “pair” is used to describe a transmitter and its corresponding receiver, while the term “user” is used only for the transmitter.

[2] It is assumed that K is divisible by M, and hence, $n = \frac{K}{M}$ is an integer number.

The channel model is assumed to be flat Rayleigh fading with the shadowing effect. The channel gain[3] between transmitter k and receiver i is represented by the random variable $\mathcal{L}_{ki}$. For $k = i$, the *direct channel gain* is defined as $\mathcal{L}_{ki} \triangleq h_{ii}$ where h_{ii} is exponentially distributed with unit mean (and unit variance). For $k \neq i$, the *cross channel gains* are defined based on a shadowing model as follows:

$$\mathcal{L}_{ki} \triangleq \begin{cases} \beta_{ki} h_{ki}, & \text{with probability} \quad \alpha \\ 0, & \text{with probability} \quad 1-\alpha, \end{cases} \tag{1}$$

where h_{ki}'s have the same distribution as h_{ii}'s, $0 \leq \alpha \leq 1$ is a fixed parameter, and the random variable β_{ki}, referred to as the *shadowing factor*, is independent of h_{ki} and satisfies the following conditions:

- $\beta_{\min} \leq \beta_{ki} \leq \beta_{\max}$, where $\beta_{\min} > 0$ and $\beta_{\max}$ is finite,
- $\mathbb{E}\big[\beta_{ki}\big] \triangleq \varpi \leq 1$.

It is also assumed that $\{\mathcal{L}_{ki}\}$ and $\{\beta_{ki}\}$ are mutually independent random variables for different (k, i).

All the channels in the network are assumed to be quasi-static block fading, i.e., the channel gains remain constant during one block and change independently from block to block. In addition, we assume that each transmitter knows its direct channel gain.

We assume a homogeneous network in the sense that all the links have the same configuration and use the same protocol. We denote the transmit power of user i by p_i, where $p_i \in \mathscr{P} \triangleq [0, \mathrm{P}_{max}]$. The vector $\mathbf{P}^{(j)} = (p_{(j-1)n+1}, ..., p_{jn})$ represents the power vector of the users in $\mathbb{C}_j$. Also, $\mathbf{P}^{(j)}_{-i}$ denotes the vector consisting of elements of $\mathbf{P}^{(j)}$ other than the i^{th} element, $i \in \mathbb{C}_j$. To simplify the notations, we assume that the noise power $\frac{N_0 W}{M}$ is normalized by P_{max}. Therefore, without loss of generality, we assume that $\mathrm{P}_{max} = 1$. Assuming that the transmitted signals are Gaussian, the interference term seen by link $i \in \mathbb{C}_j$ will be Gaussian with power

$$I_i = \sum_{\substack{k \in \mathbb{C}_j \\ k \neq i}} \mathcal{L}_{ki} p_k. \tag{2}$$

Due to the orthogonality of the allocated sub-channels, no interference is imposed from links in $\mathbb{C}_k$ on links in $\mathbb{C}_j$, $k \neq j$. Under these assumptions, the achievable data rate of each link $i \in \mathbb{C}_j$ is expressed as

$$R_i(\mathbf{P}^{(j)}, \boldsymbol{\mathcal{L}}^{(j)}_i) = \frac{W}{M} \log\left(1 + \frac{h_{ii} p_i}{I_i + \frac{N_0 W}{M}}\right), \tag{3}$$

where $\boldsymbol{\mathcal{L}}^{(j)}_i \triangleq (\mathcal{L}_{((j-1)n+1)i}, ..., \mathcal{L}_{(jn)i})$. To analyze the performance of the underlying network, we use the following performance metrics:

---

[3] In this paper, *channel gain* is defined as the square magnitude of the *channel coefficient*.

- **Network Average Sum-Rate:**

$$\bar{R}_{ave} \triangleq \mathbb{E}\left[\sum_{j=1}^{M}\sum_{l\in\mathbb{C}_j} R_l(\mathbf{P}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)})\right], \tag{4}$$

  where the expectation is computed with respect to $\boldsymbol{\mathcal{L}}_l^{(j)}$. This metric is used when there is no decoding delay constraint, i.e., decoding is performed over arbitrarily large number of blocks.

- **Network Guaranteed Sum-Rate:**

$$\bar{R}_g \triangleq \sum_{j=1}^{M}\sum_{l\in\mathbb{C}_j} \mathbb{E}_{h_{ll}}\left[R^*(h_{ll})\right], \tag{5}$$

  in which for all h_{ll}, $l \in \mathbb{C}_j$, we have

$$R^*(h_{ll}) \triangleq \sup\ R(h_{ll}), \tag{6}$$

  such that

$$\mathbb{P}\left\{R_l(\mathbf{P}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)}) < R(h_{ll})\right\} \to 0. \tag{7}$$

  This metric is useful when there exists a stringent decoding delay constraint, i.e, decoding must be performed over each separate block, and a single-layer code is used. In this case, as the transmitter does not have any information about the interference term, an outage event may occur. Network guaranteed throughput is the average sum-rate of the network which is guaranteed for all channel realizations.

B. Objectives

Part I: Maximizing the network average sum-rate: The main objective of the first part of this paper is to maximize the network average sum-rate when the interference is strong enough, i.e., $\mathbb{E}[I_i] = \omega(1)$. This is achieved by:

- Proposing a distributed and non-iterative power allocation strategy, where each user maximizes its best estimate (based on its local information, i.e., direct channel gain) of the average network sum-rate.
- Choosing the optimum value for M.

To address this problem, we first define a utility function for link $i \in \mathbb{C}_j$ ($j = 1, ..., M$) that describes the average sum-rate of the links in cluster $\mathbb{C}_j$ as follows

$$u_i(p_i, h_{ii}) \triangleq \mathbb{E}\left[\sum_{l\in\mathbb{C}_j} R_l(\mathbf{P}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)})\right], \tag{8}$$

where the expectation is computed with respect to $\{\mathcal{L}_{kl}\}_{k,l\in\mathbb{C}_j}$ excluding $k = l = i$ (namely h_{ii}). As mentioned earlier, h_{ii} is considered as the local (known) information for link i, however, all the other gains are unknown to user i which is the reason behind statistical averaging over these parameters in (8). User i selects its power using

$$\hat{p}_i = \text{arg} \max_{p_i \in \mathscr{P}} \; u_i(p_i, h_{ii}). \tag{9}$$

It will be shown that when the number of links is large and the interference is strong enough, the optimum power allocation strategy for the optimization problem in (9) is the on-off power scheme. Assuming that the channel gains change independently from block to block, each user updates its on-off decision based on its direct channel gain in each block. Given the optimum power vector $\hat{\mathbf{P}}^{(j)} = (\hat{p}_{(j-1)n+1}, ..., \hat{p}_{jn})$ obtained from (9), the network average sum-rate is then computed as (4). Next, we choose the optimum value of M such that the network average sum-rate is maximized, i.e.,

$$\hat{M} = \text{arg} \max_{M} \; \bar{R}_{ave}. \tag{10}$$

Also, for the moderate and the weak interference regimes (i.e., $\mathbb{E}[I_i] = O(1)$), we obtain upper bounds for the network average sum-rate.

Part II: Maximizing the network guaranteed sum-rate: The main objective of the second part is finding the maximum achievable network guaranteed sum-rate in the asymptotic case of $K \to \infty$. For this purpose, a lower bound and an upper-bound on the network guaranteed sum-rate are presented and shown to converge to each other as $K \to \infty$. Also, the optimum value of M is obtained.

III. NETWORK AVERAGE SUM-RATE

A. *Strong Interference Scenario* ($\mathbb{E}[I_i] = \omega(1)$)

In order to maximize the average sum-rate of the network, we first find the optimum power allocation policy. Using (8), we can express the utility function of link $i \in \mathbb{C}_j, \quad j = 1, ..., M,$ as

$$u_i(p_i, h_{ii}) = \bar{R}_i(p_i, h_{ii}) + \sum_{\substack{l \in \mathbb{C}_j \\ l \neq i}} \bar{R}_l(p_i), \tag{11}$$

where

$$\bar{R}_i(p_i, h_{ii}) = \mathbb{E}\left[\frac{W}{M} \log\left(1 + \frac{h_{ii} p_i}{I_i + \frac{N_0 W}{M}}\right)\right], \tag{12}$$

with the expectation computed with respect to I_i defined in (2), and

$$\begin{aligned} \bar{R}_l(p_i) &= \mathbb{E}\left[R_l(\mathbf{P}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)})\right] & (13)\\ &= \mathbb{E}\left[\frac{W}{M} \log\left(1 + \frac{h_{ll} p_l}{I_l + \frac{N_0 W}{M}}\right)\right] & (14)\\ &= \mathbb{E}\left[\frac{W}{M} \log\left(1 + \frac{h_{ll} p_l}{\mathcal{L}_{il} p_i + \sum_{k \neq l,i} \mathcal{L}_{kl} p_k + \frac{N_0 W}{M}}\right)\right], \quad k, l \in \mathbb{C}_j, l \neq i, & (15) \end{aligned}$$

with the expectation is computed with respect to $\mathbf{P}_{-i}^{(j)}$ and $\{\mathcal{L}_{kl}\}_{k,l\in\mathbb{C}_j}$ excluding $l = i$[4]. It is worth mentioning that the power p_i in (15) prevents the ith user from selfishly maximizing its average rate given in (12). Using the fact that all users follow the same power allocation policy, and since the channel gains $\mathcal{L}_{kl}$ are random variables with the same distributions, $\bar{R}_l(p_i)$ becomes independent of l. Thus, by dropping the index l from $\bar{R}_l(p_i)$, the utility function of link i can be simplified as

$$u_i(p_i, h_{ii}) = \bar{R}_i(p_i, h_{ii}) + (n-1)\bar{R}(p_i). \tag{16}$$

Noting that p_i depends only on the channel gain h_{ii}, in the sequel we use $p_i = g(h_{ii})$.

Lemma 1 *Let us assume* $\mathbb{E}[p_k] \triangleq q_n$, $0 < \alpha \leq 1$ *is fixed and the interference is strong enough (*$\mathbb{E}[I_i] = \omega(1)$*). Then with probability one (w. p. 1), we have*

$$I_i \ \sim \ (n-1)\hat{\alpha}q_n, \tag{17}$$

as $K \to \infty$ *(or equivalently,* $n \to \infty$*), where* $\hat{\alpha} \triangleq \alpha\varpi$*. More precisely, substituting* I_i *by* $(n-1)\hat{\alpha}q_n$ *does not change the asymptotic average sum-rate of the network.*

Proof: See Appendix I. ■

Lemma 2 *For large values of* n*, the links with a direct channel gain above* $h_{Th} = c\log n$*, where* $c > 1$ *is a constant, have negligible contribution in the network average sum-rate.*

Proof: See Appendix II. ■

From Lemma 2 and for large values of n, we can limit our attention to a subset of links for which the direct channel gain h_{ii} is less than $c\log n$, $c > 1$.

Theorem 1 *Assuming the strong interference scenario and sufficiently large* K*, the optimum power allocation policy for (9) is* $\hat{p}_i = g(h_{ii}) = U(h_{ii} - \tau_n)$*, where* $\tau_n > 0$ *is a threshold level which is a function of* n*, and* $U(.)$ *is the unit step function. Also, the maximum network average sum-rate in (4) is achieved at* $M = 1$ *and is given by*

$$\bar{R}_{ave} \sim \frac{W}{\hat{\alpha}} \log K. \tag{18}$$

Proof: The steps of the proof are as follows: First, we derive an upper bound on the utility function given in (16). Then, we prove that the optimum power allocation strategy that maximizes this upper bound is $\hat{p}_i = g(h_{ii}) = U(h_{ii} - \tau_n)$. Based on this power allocation policy, in Lemma 4, we derive the optimum threshold level τ_n. We then show that using this optimum threshold value, the maximum value of the utility function in (16) becomes asymptotically the same as the maximum value of the upper bound obtained in the first step. Finally, the proof of the theorem is completed by showing that the maximum network average sum-rate is achieved at $M = 1$.

---

[4] Note that the power of the users are random variables, since they are a deterministic function of their corresponding direct channel gains, which are random variables.

Step 1: *Upper Bound on the Utility Function*

Let us assume $\mathbb{E}[p_k] = q_n$. Using the results of Lemma 1, $\bar{R}_i(p_i, h_{ii})$ in (16) can be expressed as

$$\bar{R}_i(p_i, h_{ii}) \approx \frac{W}{M}\mathbb{E}\left[\log\left(1 + \frac{h_{ii}p_i}{(n-1)\hat{\alpha}q_n + \frac{N_0W}{M}}\right)\right] \tag{19}$$

$$\overset{(a)}{=} \frac{W}{M}\log\left(1 + \frac{h_{ii}p_i}{\lambda}\right), \tag{20}$$

as $K \to \infty$, where

$$\lambda \triangleq (n-1)\hat{\alpha}q_n + \frac{N_0W}{M}. \tag{21}$$

In the above equations, (a) follows from the fact that h_{ii} is a known parameter for user i and $p_i = g(h_{ii})$ is the optimization parameter. With a similar argument, (15) can be simplified as

$$\bar{R}(p_i) \approx \frac{W}{M}\mathbb{E}\left[\log\left(1 + \frac{h_{ll}p_l}{\mathcal{L}_{il}p_i + (n-2)\hat{\alpha}q_n + \frac{N_0W}{M}}\right)\right], \quad i \neq l \tag{22}$$

$$\overset{(a)}{=} \alpha\frac{W}{M}\mathbb{E}\left[\log\left(1 + \frac{h_{ll}p_l}{\beta_{il}h_{il}p_i + (n-2)\hat{\alpha}q_n + \frac{N_0W}{M}}\right)\right] + (1-\alpha)\frac{W}{M}\mathbb{E}\left[\log\left(1 + \frac{h_{ll}p_l}{(n-2)\hat{\alpha}q_n + \frac{N_0W}{M}}\right)\right] \tag{23}$$

$$= \frac{\alpha W}{M}\mathbb{E}\left[\log\left(1 + \frac{h_{ll}p_l}{\beta_{il}h_{il}p_i + \lambda'}\right)\right] + (1-\alpha)\frac{W}{M}\mathbb{E}\left[\log\left(1 + \frac{h_{ll}p_l}{\lambda'}\right)\right], \tag{24}$$

as $K \to \infty$, where the expectation is computed with respect to h_{ll}, h_{il}, p_l and β_{il}, and $\lambda' \triangleq (n-2)\hat{\alpha}q_n + \frac{N_0W}{M}$. Also, (a) comes from the shadowing model described in (1). Using (20), (24), and the inequality $\log(1+x) \leq x$, the utility function in (16) is upper bounded as[5]

$$u_i(p_i, h_{ii}) \leq \frac{W}{M}\frac{h_{ii}}{\lambda}p_i + n\frac{\alpha W}{M}\mathbb{E}\left[\frac{h_{ll}p_l}{\beta_{il}h_{il}p_i + \lambda'}\right] + n(1-\alpha)\frac{W}{M\lambda'}\mathbb{E}[h_{ll}p_l]. \tag{25}$$

Noting that h_{ll} is independent of h_{il}, $i \neq l$, we have

$$\mathbb{E}\left[\frac{h_{ll}p_l}{\beta_{il}h_{il}p_i + \lambda'}\middle|\beta_{il}\right] = \mu\int_0^\infty \frac{e^{-y}}{y\beta_{il}p_i + \lambda'}dy \tag{26}$$

$$= -\frac{\mu}{\beta_{il}p_i}e^{\frac{\lambda'}{\beta_{il}p_i}}\mathrm{Ei}\left(-\frac{\lambda'}{\beta_{il}p_i}\right), \tag{27}$$

where

$$\mu \triangleq \mathbb{E}[h_{ll}p_l], \tag{28}$$

---

[5] Note that the factor $(n-1)$ in (16) is replaced by n in (25), which does not affect the validity of the equation.

and $\mathrm{Ei}(x) \triangleq -\int_{-x}^{\infty}\frac{e^{-t}}{t}dt,\ x<0$ is the *exponential-integral function* [34]. Thus, the right hand side of (25) is simplified as

$$u_i(p_i,h_{ii}) \leq \frac{W}{M}\frac{h_{ii}}{\lambda}p_i - n\frac{\alpha\mu W}{M}\mathbb{E}\left[\frac{1}{\beta_{il}p_i}e^{\frac{\lambda'}{\beta_{il}p_i}}\mathrm{Ei}\left(-\frac{\lambda'}{\beta_{il}p_i}\right)\right] + n(1-\alpha)\frac{W}{M}\frac{\mu}{\lambda'}, \tag{29}$$

where the expectation is computed with respect to β_{il}. An asymptotic expansion of $\mathrm{Ei}(x)$ can be obtained as [34, p. 951]

$$\mathrm{Ei}(x) = \frac{e^x}{x}\left[\sum_{k=0}^{L-1}\frac{k!}{x^k} + O(|x|^{-L})\right]; \quad L=1,2,..., \tag{30}$$

as $x \to -\infty$. Setting $L=4$, we can rewrite (29) as

$$\begin{aligned} u_i(p_i,h_{ii}) \quad &\leq \quad \frac{W}{M}\frac{h_{ii}}{\lambda}p_i + n\frac{\alpha W\mu}{M\lambda'}\mathbb{E}\left[\left(1-\frac{\beta_{il}p_i}{\lambda'}+2\left(\frac{\beta_{il}p_i}{\lambda'}\right)^2-6\left(\frac{\beta_{il}p_i}{\lambda'}\right)^3\right)\right]+ \\ & \quad\quad n\frac{\alpha W\mu}{M\lambda'}\mathbb{E}\left[O\left(\left|\frac{\beta_{il}p_i}{\lambda'}\right|^4\right)\right] + n(1-\alpha)\frac{W\mu}{M\lambda'} \qquad (31) \\ &\overset{(a)}{\approx} \quad \frac{W}{M}\frac{h_{ii}}{\lambda}p_i + n\frac{\alpha W\mu}{M\lambda'}\left(1-\frac{\varpi p_i}{\lambda'}+2\kappa\left(\frac{p_i}{\lambda'}\right)^2-6\eta\left(\frac{p_i}{\lambda'}\right)^3\right) + n(1-\alpha)\frac{W\mu}{M\lambda'} \qquad (32) \\ &\triangleq \quad \Xi_i(p_i,h_{ii}), \qquad (33) \end{aligned}$$

as $\lambda' \to \infty$, where $\kappa \triangleq \mathbb{E}\left[\beta_{ki}^2\right]$ and $\eta \triangleq \mathbb{E}\left[\beta_{ki}^3\right]$, and (a) follows from the fact that for large values of λ', the term $\mathbb{E}\left[O\left(\left|\frac{\beta_{il}p_i}{\lambda'}\right|^4\right)\right]$ can be ignored.

Step 2: *Optimum Power Allocation Policy for* $\Xi_i(p_i,h_{ii})$

Using the fact that $p_i \in [0,1]$, the second-order derivative of (32) in terms of p_i, $\frac{\partial^2\Xi_i(p_i,h_{ii})}{\partial p_i^2} = n\frac{\alpha W\mu}{M\lambda'}\left(\frac{4\kappa}{\lambda'^2}-\frac{36\eta}{\lambda'^3}p_i\right)$, is positive[6] as $\lambda' \to \infty$. Thus, (32) is a *convex* function of p_i. It is known that a convex function attains its maximum at one of its extreme points[7] of its domain [35]. In other words, the optimum power that maximizes (32) is $\hat{p}_i \in \{0,1\}$. To show that this optimum power is in the form of a unit step function, it is sufficient to prove that $p_i = g(h_{ii})$ is a monotonically increasing function of h_{ii}.

Suppose that the optimum power that maximizes $\Xi_i(p_i,h_{ii})$ is $p_i=1$. Also, let us define $h_{ii}^{'} \triangleq h_{ii}+\delta$, where $\delta>0$. From (32), it is clear that $\Xi_i(p_i,h_{ii})$ is a monotonically increasing function of h_{ii}, i.e.,

$$\Xi_i(p_i=1,h_{ii}^{'}) > \Xi_i(p_i=1,h_{ii}). \tag{34}$$

On the other hand, since the optimum power is $p_i=1$, we conclude that

$$\Xi_i(p_i=1,h_{ii}) > \Xi_i(p_i=0,h_{ii}). \tag{35}$$

Using the fact that $\Xi_i(p_i=0,h_{ii}) = \Xi_i(p_i=0,h_{ii}^{'})$, we arrive at the following inequality

$$\Xi_i(p_i=1,h_{ii}^{'}) > \Xi_i(p_i=0,h_{ii}^{'}). \tag{36}$$

---

[6] It is observed from (30) and (32) that for any value of $L>4$, the second-order derivative of (32) in terms of p_i is positive too.

[7] In the power domain $\mathscr{P}=[0,1]$, the extreme points are 0 and 1.

From (34)-(36), it is concluded that $g(h_{ii})$ is a monotonically increasing function of h_{ii}. Consequently, the optimum power allocation strategy that maximizes $\Xi_i(p_i, h_{ii})$ is a unit step function, i.e.,

$$\hat{p}_i = \begin{cases} 1, & \text{if} \quad h_{ii} > \tau_n \\ 0, & \text{Otherwise}, \end{cases} \tag{37}$$

where τ_n is a threshold level to be determined. We call this the *threshold-based on-off power allocation strategy*. It is observed that the optimum power $\hat{p}_i$ is a Bernoulli random variable with parameter q_n, i.e.,

$$f(\hat{p}_i) = \begin{cases} q_n, & \hat{p}_i = 1, \\ 1 - q_n, & \hat{p}_i = 0, \end{cases} \tag{38}$$

where $f(.)$ is the probability mass function (pmf) of $\hat{p}_i$. We conclude from (37) and (38) that the probability of link activation in each cluster is $q_n \triangleq \mathbb{P}\left\{h_{ii} > \tau_n\right\} = e^{-\tau_n}$ which is a function of n.

Step 3: *Optimum Threshold Level* τ_n

From Step 1, it is observed that for every value of p_i we have

$$u_i(p_i, h_{ii}) \leq \Xi_i(p_i, h_{ii}). \tag{39}$$

The above inequality is also valid for the optimum power $\hat{p}_i$ obtained in Step 2. Thus, using the fact that for $X \leq Y$, $\mathbb{E}[X] \leq \mathbb{E}[Y]$, we conclude

$$\mathbb{E}[u_i(\hat{p}_i, h_{ii})] \leq \mathbb{E}[\Xi_i(\hat{p}_i, h_{ii})], \tag{40}$$

where the expectations are computed with respect to h_{ii}. In the following lemmas, we first derive the optimum threshold level τ_n that maximizes $\mathbb{E}[\Xi_i(\hat{p}_i, h_{ii})]$, and then prove that this quantity is asymptotically the same as the optimum threshold level maximizing[8] $\mathbb{E}[u_i(\hat{p}_i, h_{ii})]$, assuming an on-off power scheme. We also show that the maximum value of $\mathbb{E}[u_i(\hat{p}_i, h_{ii})]$ (assuming an on-off power scheme) is the same as the optimum value of $\mathbb{E}[\Xi_i(\hat{p}_i, h_{ii})]$, proving the desired result.

Lemma 3 *For large values of n and given $0 < \alpha \leq 1$, the optimum threshold level that maximizes $\mathbb{E}[\Xi_i(\hat{p}_i, h_{ii})]$ is computed as*

$$\hat{\tau}_n \sim \log n. \tag{41}$$

Also, the maximum value of $\mathbb{E}[\Xi_i(\hat{p}_i, h_{ii})]$ scales as $\frac{W}{M\hat{\alpha}} \log n$.

Proof: See Appendix III. ■

Lemma 4 *For large values of n and given $0 < \alpha \leq 1$,*

---

[8] In fact, since the threshold τ_n is fixed and does not depend on a specific realization of h_{ii}, finding the optimum value of τ_n requires averaging the utility function over all realizations of h_{ii}.

i) The optimum threshold level that maximizes $\mathbb{E}[u_i(\hat{p}_i, h_{ii})]$ is computed as

$$\hat{\tau}_n = \log n - 2\log\log n + O(1), \tag{42}$$

ii) The probability of link activation in each cluster is given by

$$q_n = \delta \frac{\log^2 n}{n}, \tag{43}$$

where $\delta > 0$ is a constant,

iii) The maximum value of $\mathbb{E}[u_i(\hat{p}_i, h_{ii})]$ scales as $\frac{W}{M\hat{\alpha}} \log n$.

Proof: See Appendix IV. ■

Step 4: *Optimum Power Allocation Strategy that Maximize $u_i(p_i, h_{ii})$*

In order to prove that the utility function in (16) is asymptotically the same as the upper bound $\Xi_i(p_i, h_{ii})$ obtained in (32), it is sufficient to show that the low SINR conditions in (20) and (24) are satisfied. Using (20), (21) and (43), the SINR is equal to $\frac{h_{ii}p_i}{\lambda}$, where

$$\lambda \approx \hat{\alpha}\delta \log^2 n + \frac{N_0 W}{M}. \tag{44}$$

It is observed that λ goes to infinity as $n \to \infty$. On the other hand, since we are limiting our attention to links with $h_{ii} < h_{Th} = c \log n$, we have

$$\frac{h_{ii}p_i}{\lambda} = O\left(\frac{1}{\log n}\right), \tag{45}$$

when $n \to \infty$. Thus, for large values of n, the low SINR condition, $\frac{h_{ii}p_i}{\lambda} \ll 1$, is satisfied. With a similar argument, the low SINR condition for (24) is satisfied. Hence, we can use the approximation $\log(1+x) \approx x$, for $x \ll 1$, to simplify (20) and (24) as follows:

$$\bar{R}_i(p_i, h_{ii}) \approx \frac{W}{M}\frac{h_{ii}}{\lambda} p_i, \tag{46}$$

$$\bar{R}(p_i) \approx \frac{\alpha W}{M} \mathbb{E}\left[\frac{h_{ll}p_l}{\beta_{il}h_{il}p_i + \lambda'}\right] + (1-\alpha)\frac{W}{M\lambda'}\mathbb{E}\left[h_{ll}p_l\right]. \tag{47}$$

Consequently, the utility function $u_i(p_i, h_{ii})$ is the same as the upper bound $\Xi_i(p_i, h_{ii})$ obtained in (32), when $n \to \infty$. Thus, the optimum power allocation strategy for (9) is the same as the optimum power allocation policy that maximizes $\Xi_i(p_i, h_{ii})$.

Step 5: *Maximum Average Network Sum-rate*

Using (8), the average utility function of each user i, $\mathbb{E}\left[u_i(\hat{p}_i, h_{ii})\right], \;\; i \in \mathbb{C}_j$, is the same as the average sum-rate of the links in cluster $\mathbb{C}_j$ represented by

$$\bar{R}^{(j)}_{ave} \triangleq \sum_{i \in \mathbb{C}_j} \mathbb{E}\left[R_i(\hat{\mathbf{P}}^{(j)}, \boldsymbol{\mathcal{L}}^{(j)}_i)\right], \quad j = 1, ..., M. \tag{48}$$

where $\hat{\mathbf{P}}^{(j)}$ is the on-off powers vector of the links in cluster $\mathbb{C}_j$. In this case, the network average sum-rate defined in (4) can be written as

$$\begin{aligned} \bar{R}_{ave} &= \sum_{j=1}^{M} \bar{R}_{ave}^{(j)} && (49) \\ &\overset{(a)}{\approx} \frac{W\hat{\tau}_n}{\hat{\alpha}}, && (50) \end{aligned}$$

where (a) follows from (D-20) of Appendix IV. Using (42), and noting that $n = \dfrac{K}{M}$, we have

$$\bar{R}_{ave} \sim \frac{W}{\hat{\alpha}} \log \frac{K}{M}. \tag{51}$$

Step 6: *Optimum Spectrum Allocation*

According to (50), the network average sum-rate is a monotonically increasing function of $\hat{\tau}_n$. Rewriting equation (D-15) of Appendix IV, which gives the optimum threshold value for the on-off scheme:

$$- e^{-\hat{\tau}_n} \log \left(1 + \frac{\hat{\tau}_n e^{\hat{\tau}_n}}{n\hat{\alpha}}\right) + \frac{1 + \hat{\tau}_n}{n\hat{\alpha} + \hat{\tau}_n e^{\hat{\tau}_n}} = 0, \tag{52}$$

it can be shown that[9]

$$\hat{\tau}_n^2 e^{\hat{\tau}_n} \approx n\hat{\alpha}, \tag{53}$$

which implies that $\hat{\tau}_n$ is an increasing function of n. Therefore, the average sum-rate of the network is an increasing function of n and consequently, noting that $n = \frac{K}{M}$, is a decreasing function of M. Hence, the maximum average sum-rate of the network for the strong interference scenario and $0 < \alpha < 1$ is obtained at $M = 1$ and this completes the proof of the theorem. ■

Motivated by Theorem 1, we describe the proposed threshold-based on-off power allocation strategy for single-hop wireless networks. Based on this scheme, all users perform the following steps during each block:

1- Based on the direct channel gain, the transmission policy is

$$\hat{p}_i = \begin{cases} 1, & \text{if} \quad h_{ii} > \tau_n \\ 0, & \text{Otherwise}. \end{cases}$$

2- Knowing its corresponding direct channel gain, each active user i transmits with full power and rate

$$R_i = \log \left(1 + \frac{h_{ii}}{(n-1)\hat{\alpha} e^{-\tau_n} + \frac{N_0 W}{M}}\right). \tag{54}$$

3- Decoding is performed over sufficiently large number of blocks, yielding the average rate of $\frac{W}{\hat{\alpha}K} \log K$ for each user, and the average sum-rate of $\frac{W}{\hat{\alpha}} \log K$ in the network.

---

[9] In deriving (53), we have used the fact that $\frac{\hat{\tau}_n e^{\hat{\tau}_n}}{n\hat{\alpha}} \ll 1$, which is feasible based on the solution given in (42).

Remark 1- Theorem 1 states that the average sum-rate of the network for fixed M depends on the value of $\hat{\alpha} = \alpha\varpi$ and scales as $\frac{W}{\hat{\alpha}} \log \frac{K}{M}$. Also, for values of M such that $\log M = o(\log K)$, the network average sum-rate scales as $\frac{W}{\hat{\alpha}} \log K$.

Remark 2- Let m_j denote the number of active links in $\mathbb{C}_j$. Lemma 4 states that the optimum selection of the threshold value yields $\mathbb{E}[m_j] = nq_n = \Theta\left(\log^2 n\right)$. More precisely, it can be shown that the optimum number of active users scales as $\Theta\left(\log^2 n\right)$, with probability one.

B. Moderate and Weak Interference Scenarios ($\mathbb{E}[I_i] = O(1)$)

Theorem 2 *Let us assume K is large and M is fixed. Then,*

i) For the moderate interference (i.e., $\mathbb{E}[I_i] = \Theta(1)$), the network average sum-rate is bounded by $\bar{R}_{ave} \le \Theta(\log n)$.

ii) For the weak interference (i.e., $\mathbb{E}[I_i] = o(1)$), the network average sum-rate is bounded by $\bar{R}_{ave} \le o(\log n)$.

Proof: i) From (4), we have

$$\begin{aligned}
\bar{R}_{ave} &= \sum_{j=1}^{M} \sum_{l \in \mathbb{C}_j} \mathbb{E}\left[\frac{W}{M} \log\left(1 + \frac{h_{ll}\hat{p}_l}{I_l + \frac{N_0 W}{M}}\right)\right] && (55)\\
&\overset{(a)}{\le} \sum_{j=1}^{M} \sum_{l \in \mathbb{C}_j} \frac{W}{M} \mathbb{E}\left[\log\left(1 + \frac{\hat{p}_l c \log n}{I_l + \frac{N_0 W}{M}}\right)\right] && (56)\\
&\le \sum_{j=1}^{M} \sum_{l \in \mathbb{C}_j} \frac{W}{M} \mathbb{E}\left[\log\left(1 + \frac{\hat{p}_l c \log n}{\frac{N_0 W}{M}}\right)\right] && (57)\\
&\overset{(b)}{\le} \sum_{j=1}^{M} \sum_{l \in \mathbb{C}_j} \frac{W}{M} \log\left(1 + \frac{c q_n \log n}{\frac{N_0 W}{M}}\right) && (58)\\
&\overset{(c)}{\le} \frac{cM}{N_0} n q_n \log n, && (59)
\end{aligned}$$

where (a) follows from Lemma 2, which implies that the realizations in which $h_{ll} > c \log n$ for some $c > 1$ has negligible contribution in the network average sum-rate, (b) results from the *Jensen's inequality*, $\mathbb{E}\left[\log x\right] \le \log(\mathbb{E}\left[x\right])$, $x > 0$. Also, (c) follows from the fact that $\log(1+x) \le x$, $x > 0$. Since for the moderate interference, $\mathbb{E}[I_i] = \hat{\alpha} n q_n = \Theta(1)$, and using the fact that M is fixed, we come up with the following inequality

$$\begin{aligned}
\bar{R}_{ave} &\le \frac{cM}{\hat{\alpha} N_0} \Theta(1) \log n && (60)\\
&= \Theta(\log n). && (61)
\end{aligned}$$

ii) For the weak interference scenario, where $\mathbb{E}[I_i] = \hat{\alpha} n q_n = o(1)$, and similar to the part (i), it is concluded from (59) that

$$\begin{aligned} \bar{R}_{ave} &\leq \frac{cM}{\hat{\alpha} N_0} o(1) \log n &(62)\\ &= o(\log n). &(63) \end{aligned}$$

■

Remark 3- It is concluded from Theorems 1 and 2 that the maximum average sum-rate of the proposed network is scaled as $\Theta(\log K)$.

C. M Not Fixed (Scaling With K)

So far, we assume that M is fixed, i.e., it does not scale with K. In the following, we present some results for the case that M scales with K[10]. It should be noted that the results for $M = o(K)$ is the same as the results in Theorem 1.

Theorem 3 *In the network with the on-off power allocation strategy, if $M = \Theta(K)$ and $0 < \alpha < 1$, then the maximum network average sum-rate in (4) is less than that of $M = 1$. Consequently, the maximum average sum-rate of the network for every value of $1 \leq M \leq K$ is achieved at $M = 1$.*

Proof: See Appendix V. ■

Remark 4- According to the shadow-fading model proposed in (1), it is seen that for $\alpha = 0$, with probability one, $\mathcal{L}_{ki} = 0, \; k \neq i$. This implies that no interference exists in each cluster. In this case, the maximum average sum-rate of the network is clearly achieved by all users in the network transmitting at full power. It can be shown that for every value of $1 \leq M \leq K$, the maximum network average sum-rate for $\alpha = 0$ is achieved at $M = 1$ (See Appendix VI for the proof).

Remark 5- Noting that for $M = K$ only one user exists in each cluster, all the users can communicate using an interference free channel. It can be shown that for $M = K$ and every value of $0 \leq \alpha \leq 1$, the network average sum-rate is asymptotically obtained as

$$\bar{R}_{ave} \approx W(\log K - \log N_0 W - \boldsymbol{\gamma}), \tag{64}$$

where $\boldsymbol{\gamma}$ is Euler's constant (See Appendix VII for the proof). Therefore, for every value of $0 < \alpha < 1$, it is observed that the average sum-rate of the network in (64) is less than that of $M = 1$ obtained in (18).

Remark 6- Note that for $M = 1$, in which the average number of active links scales as $\Theta(\log^2 K)$ (in the optimum on-off scheme), we have significant energy saving in the network as compared to the case of $M = K$, in which all the users transmit with full power.

---

[10] Obviously, we consider the values of M which are in the interval $[1, K]$.

D. Numerical Results

So far, we have analyzed the average sum-rate of the network in terms of M and $\hat{\alpha}$, in the asymptotic case of $K \to \infty$. For finite number of users, we have evaluated the network average sum-rate versus the number of clusters (M) through simulation. For this case, we assume that all the users in the network follow the threshold-based on-off power allocation policy, using the optimum threshold value. In addition, the shadowing effect is assumed to be *lognormal* distributed with mean $\varpi \leq 1$ and variance 1. Fig. 1 shows the average sum-rate of the network versus M for $K = 20$ and $K = 40$, and different values of α and ϖ. It is observed from this figure that the average sum-rate of the network is a monotonically decreasing function of M for every value of (α, ϖ), which implies that the maximum value of $\bar{R}_{ave}$ is achieved at $M = 1$.

Based on the above arguments, we have plotted the average sum-rate of the network versus K for $M = 1$ and different values of (α, ϖ). It is observed from Fig. 2 that the network average sum-rate depends strongly on the values of (α, ϖ).

IV. NETWORK GUARANTEED SUM-RATE

Recalling the definition of the network guaranteed sum-rate in (5), in this section we aim to find the maximum achievable guaranteed sum-rate of the network, as well as the optimum power allocation scheme and the optimum value of M.

Theorem 4 *The guaranteed sum-rate of the underlying network in the asymptotic case of $K \to \infty$ is obtained by*

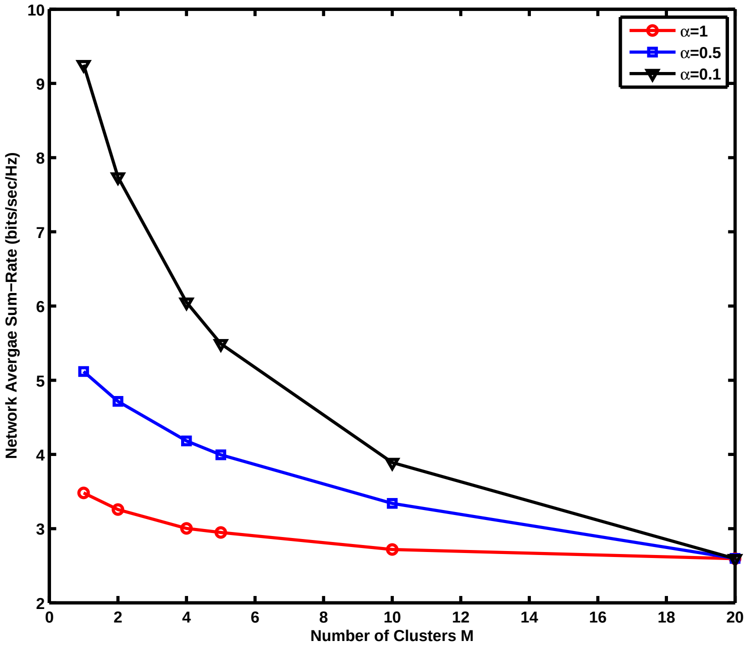
$$\bar{R}_g \sim \frac{W}{\hat{\alpha}} \log K, \tag{65}$$

which is achievable by the decentralized on-off power allocation scheme.

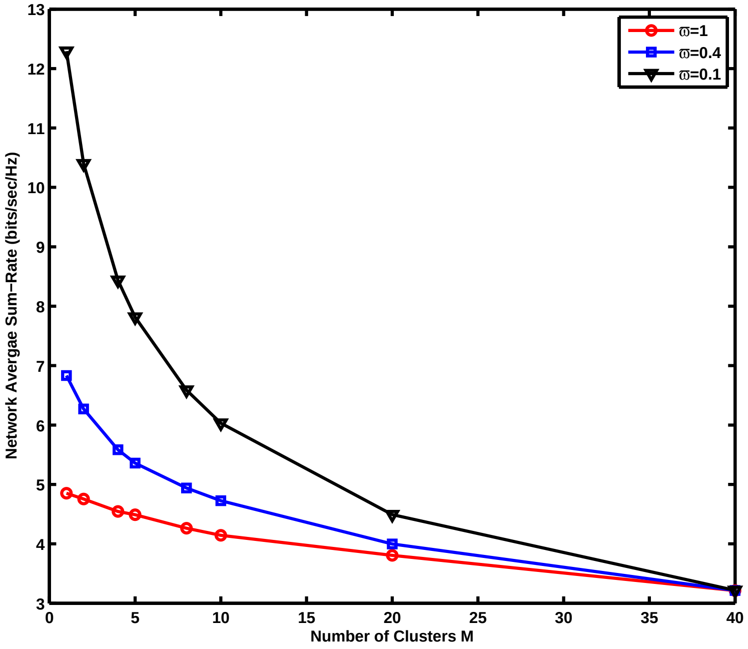
Proof: In order to compute the guaranteed rate for link $l \in \mathbb{C}_j$, we first define the corresponding outage event as follows:

$$\begin{aligned} \mathcal{O}_l^{(j)} &\equiv \left\{ R_l(\mathbf{P}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)}) < R(h_{ll}) \right\} & (66) \\ &\equiv \left\{ \log\left(1 + \frac{p_l h_{ll}}{I_l + \frac{N_0 W}{M}}\right) < R(h_{ll}) \right\}. & (67) \end{aligned}$$

In the following, we give an upper-bound and a lower-bound for $\bar{R}_g$ and show that these bounds converge to each other as $K \to \infty$ (or equivalently, $n \to \infty$).

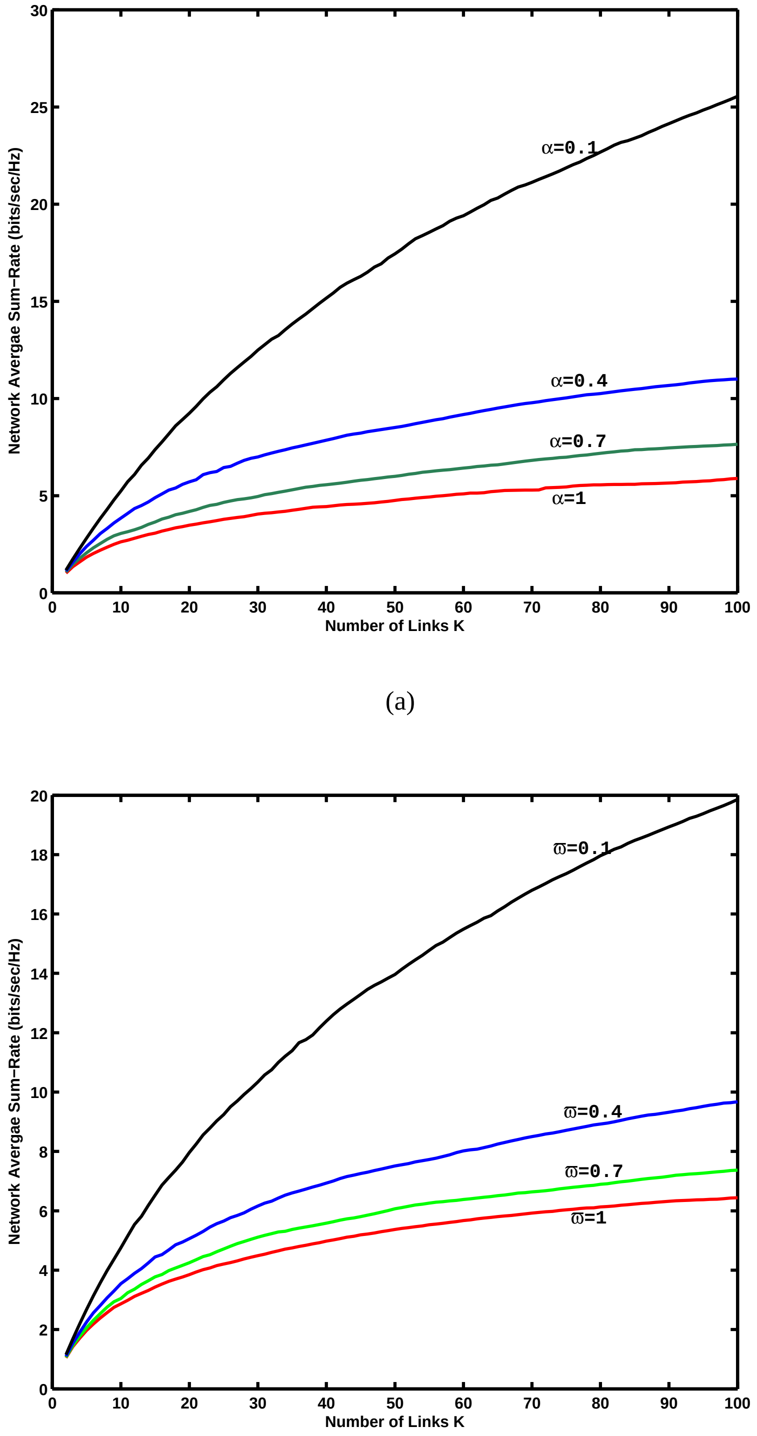


(a)



(b)

Fig. 1. Network average sum-rate vs. M for a) $K = 20$, $\alpha = 1,\ 0.5,\ 0.1$ and shadowing model with $\varpi = 0.5$ and variance 1, and b) $K = 40$, $\alpha = 0.5$ and shadowing model with $\varpi = 1,\ 0.4,\ 0.1$ and variance 1.



(a)

(b)

Fig. 2. Network average sum-rate vs. K for $M = 1$ and a) shadowing model with $\varpi = 0.5$ and variance 1, and $\alpha = 1,\ 0.7,\ 0.4,\ 0.1$, and b) shadowing model with $\varpi = 1,\ 0.7,\ 0.4,\ 0.1$ and variance 1, and $\alpha = 0.5$.

Upper-bound: An upper-bound on the guaranteed sum-rate can be given by lower-bounding the outage probability as follows:

$$\begin{aligned}\mathbb{P}\left\{\mathcal{O}_l^{(j)}\right\} &\geq \mathbb{P}\left\{\frac{p_l h_{ll}}{I_l+\frac{N_0 W}{M}} < R(h_{ll})\right\} && (68)\\ &= \mathbb{P}\left\{p_l h_{ll} - \frac{N_0 W}{M} R(h_{ll}) < I_l R(h_{ll})\right\}, && (69)\end{aligned}$$

in which we have used the fact that $\log(1+x) \leq x$. Denoting $\nu = h_{ll}$, we can write

$$\begin{aligned}\mathbb{P}\left\{\mathcal{O}_l^{(j)}\right\} &\overset{(a)}{\geq} \mathbb{P}\left\{e^{-I_l \xi(\nu) R(\nu)} \leq e^{\xi(\nu)\left(\frac{N_0 W}{M} R(\nu) - p_l \nu\right)}\right\} && (70)\\ &\overset{(b)}{\geq} 1 - e^{-\xi(\nu)\left(\frac{N_0 W}{M} R(\nu) - p_l \nu\right)} \mathbb{E}\left[e^{-I_l \xi(\nu) R(\nu)}\right], && (71)\end{aligned}$$

for some positive $\xi(\nu)$. In the above equation, (a) results from (69), noting that $\xi(\nu) > 0$, and (b) follows from Markov's inequality [36, p. 77], and the expectation is taken with respect to I_l. The above equation implies that finding an upper-bound for $\mathbb{E}\left[e^{-I_l \xi(\nu) R(\nu)}\right]$ is sufficient for the lower-bounding the outage probability. For this purpose, using (2), we can write

$$\begin{aligned}\mathbb{E}\left[e^{-I_l \xi(\nu) R(\nu)}\right] &= \mathbb{E}\left[e^{-\xi(\nu) R(\nu) \sum_{\substack{k\in\mathbb{C}_j\\ k\neq l}} \mathcal{L}_{kl} p_k}\right] && (72)\\ &\overset{(a)}{=} \prod_{\substack{k\in\mathbb{C}_j\\ k\neq l}} \mathbb{E}\left[e^{-\xi(\nu) R(\nu) \mathcal{L}_{kl} p_k}\right] && (73)\\ &\overset{(b)}{=} \prod_{\substack{k\in\mathbb{C}_j\\ k\neq l}} \mathbb{E}\left[e^{-\xi(\nu) R(\nu) u_{kl} \beta_{kl} h_{kl} p_k}\right] && (74)\\ &\overset{(c)}{=} \left(\mathbb{E}\left[e^{-\xi(\nu) R(\nu) u_{kl} \beta_{kl} h_{kl} p_k}\right]\right)^{n-1}, \; k \neq l. && (75)\end{aligned}$$

In the above equation, (a) follows from the fact that $\{\mathcal{L}_{kl}\}_{k\in\mathbb{C}_j}$ with $k \neq l$, and $\{p_k\}_{k\in\mathbb{C}_j}$ are mutually independent random variables, (b) results from writing $\mathcal{L}_{kl}$ as $u_{kl}\beta_{kl}h_{kl}$ (from (1)), in which u_{kl} is an indicator variable which takes zero when $\mathcal{L}_{kl} = 0$ and one, otherwise. (c) follows from the symmetry which incurs that all the terms $\mathbb{E}\left[e^{-\xi(\nu) R(\nu) u_{kl} \beta_{kl} h_{kl} p_k}\right]$, $k \in \mathbb{C}_j$, are equal. Noting that u_{kl}, β_{kl}, h_{kl}, and

p_k are independent of each other, we have

$$\begin{aligned}
\mathbb{E}\left[e^{-\xi(\nu)R(\nu)u_{kl}\beta_{kl}h_{kl}p_k}\right] &= \mathbb{E}_{\beta_{kl}}\left[\mathbb{E}_{h_{kl}}\left[\mathbb{E}_{u_{kl}}\left[\mathbb{E}_{p_k}\left[e^{-\xi(\nu)R(\nu)u_{kl}\beta_{kl}h_{kl}p_k}\right]\right]\right]\right] && (76)\\
&\overset{(a)}{\leq} \mathbb{E}_{\beta_{kl}}\left[\mathbb{E}_{h_{kl}}\left[\mathbb{E}_{u_{kl}}\left[(1-q_n)+q_n e^{-\xi(\nu)R(\nu)u_{kl}\beta_{kl}h_{kl}}\right]\right]\right] && (77)\\
&\overset{(b)}{=} \mathbb{E}_{\beta_{kl}}\left[\mathbb{E}_{h_{kl}}\left[(1-q_n)+q_n\left(1-\alpha+\alpha e^{-\xi(\nu)R(\nu)\beta_{kl}h_{kl}}\right)\right]\right] && (78)\\
&\overset{(c)}{=} \mathbb{E}_{\beta_{kl}}\left[1-\alpha q_n+\frac{\alpha q_n}{1+\beta_{kl}\xi(\nu)R(\nu)}\right] && (79)\\
&= \mathbb{E}_{\beta_{kl}}\left[1-\frac{\alpha q_n\beta_{kl}\xi(\nu)R(\nu)}{1+\beta_{kl}\xi(\nu)R(\nu)}\right] && (80)\\
&\overset{(d)}{\leq} 1-\frac{\alpha q_n\varpi\xi(\nu)R(\nu)}{1+\beta_{\max}\xi(\nu)R(\nu)} && (81)\\
&\overset{(e)}{\leq} e^{-\frac{\hat{\alpha}q_n\xi(\nu)R(\nu)}{1+\beta_{\max}\xi(\nu)R(\nu)}}. && (82)
\end{aligned}$$

In the above equation, (a) follows from the fact that $e^{-\theta x}\leq(1-x)+xe^{-\theta}$, $\forall\theta\geq 0$ and $0\leq x\leq 1$, noting that $\mathbb{E}[p_k]=q_n$. (b) results from the definition of u_{kl}, which is an indicator variable taking zero with probability $1-\alpha$ and one, with probability α. (c) follows from the fact that as h_{kl} is exponentially-distributed, we have $\mathbb{E}_{h_{kl}}\left[e^{-\xi(\nu)R(\nu)\beta_{kl}h_{kl}}\right]=\frac{1}{1+\beta_{kl}\xi(\nu)R(\nu)}$. (d) results from the facts that $\beta_{kl}\leq\beta_{\max}$ and $\mathbb{E}[\beta_{kl}]=\varpi$. Finally, (e) follows from the fact that $1-x\leq e^{-x}$, $\forall x$ and noting that $\alpha\varpi=\hat{\alpha}$.

Combining (75) and (82) and substituting into (71) yields

$$\begin{aligned}
\mathbb{P}\left\{\mathcal{O}_l^{(j)}\right\} &\geq 1-e^{-\xi(\nu)\left(\frac{N_0W}{M}R(\nu)-p_l\nu\right)}e^{-\frac{(n-1)\hat{\alpha}q_n\xi(\nu)R(\nu)}{1+\beta_{\max}\xi(\nu)R(\nu)}} && (83)\\
&= 1-e^{-\xi(\nu)R(\nu)\left(\frac{(n-1)\hat{\alpha}q_n}{1+\beta_{\max}\xi(\nu)R(\nu)}+\frac{N_0W}{M}\right)\left(1-\frac{t(\nu)}{R(\nu)}\right)}, && (84)
\end{aligned}$$

where $t(\nu)\triangleq\frac{p_l\nu}{\frac{(n-1)\hat{\alpha}q_n}{1+\beta_{\max}\xi(\nu)R(\nu)}+\frac{N_0W}{M}}$.

Consider the cases of $\mathbb{E}\{I_l\}=\omega(1)$ (strong interference) or $\mathbb{E}\{I_l\}=\Theta(1)$ (moderate interference). Let us define $\gamma\triangleq\min\left(1,\frac{M(n-1)q_n\hat{\alpha}}{N_0W}\right)$. Setting $\xi(\nu)\triangleq\frac{\frac{\gamma}{2}\frac{N_0W}{M}}{\beta_{\max}R(\nu)\left((n-1)\hat{\alpha}q_n-\frac{\gamma}{2}\frac{N_0W}{M}\right)}$, we have $\frac{(n-1)\hat{\alpha}q_n}{1+\beta_{\max}\xi(\nu)R(\nu)}+\frac{N_0W}{M}=(n-1)\hat{\alpha}q_n+(1-\frac{\gamma}{2})\frac{N_0W}{M}$, and as a result,

$$\begin{aligned}
\mathbb{P}\left\{\mathcal{O}_l^{(j)}\right\} &\geq 1-e^{-\frac{\frac{\gamma}{2}\frac{N_0W}{M}\left[(n-1)\hat{\alpha}q_n+(1-\frac{\gamma}{2})\frac{N_0W}{M}\right]}{\beta_{\max}\left[(n-1)\hat{\alpha}q_n-\frac{\gamma}{2}\frac{N_0W}{M}\right]}\left(1-\frac{t(\nu)}{R(\nu)}\right)} && (85)\\
&\geq 1-e^{-\frac{\gamma N_0W}{2M\beta_{\max}}\left(1-\frac{t(\nu)}{R(\nu)}\right)}. && (86)
\end{aligned}$$

Since $\frac{\gamma N_0W}{2M\beta_{\max}}=\Theta(1)$, it follows that the necessary condition to have $\mathbb{P}\left\{\mathcal{O}_l^{(j)}\right\}\to 0$ is having $R(\nu)\lesssim t(\nu)=\frac{p_l\nu}{(n-1)\hat{\alpha}q_n+(1-\frac{\gamma}{2})\frac{N_0W}{M}}$. In other words,

$$R^*(\nu)\lesssim\frac{p_l\nu}{(n-1)\hat{\alpha}q_n+(1-\frac{\gamma}{2})\frac{N_0W}{M}}, \qquad (87)$$

which implies that $\bar{R}_g$ defined in (5) is upper bounded by

$$\begin{aligned} \bar{R}_g &\lesssim nW\mathbb{E}_\nu\left[\frac{p_l\nu}{(n-1)\hat{\alpha}q_n+(1-\frac{\gamma}{2})\frac{N_0W}{M}}\right] && (88)\\ &= \frac{nW\mathbb{E}_\nu\left[p_l\nu\right]}{(n-1)\hat{\alpha}q_n+(1-\frac{\gamma}{2})\frac{N_0W}{M}}. && (89)\end{aligned}$$

Now, defining $\Psi_n \triangleq \log n + 2\log\log n$, we have

$$\begin{aligned} \mathbb{E}_\nu\left[p_l\nu\right] &\leq \mathbb{E}\left[p_l\nu|\nu\leq\Psi_n\right]\mathbb{P}\{\nu\leq\Psi_n\}+\mathbb{E}\left[p_l\nu|\nu>\Psi_n\right]\mathbb{P}\{\nu>\Psi_n\} && (90)\\ &\overset{(a)}{\leq} q_n\Psi_n+\mathbb{E}\left[\nu|\nu>\Psi_n\right]\mathbb{P}\{\nu>\Psi_n\} && (91)\\ &\overset{(b)}{=} q_n\Psi_n+(\Psi_n+1)e^{-\Psi_n} && (92)\\ &\overset{(c)}{\sim} q_n\log n. && (93)\end{aligned}$$

In the above equation, (a) comes from the facts that

$$\mathbb{E}\left[p_l\nu|\nu\leq\Psi_n\right]\mathbb{P}\{\nu\leq\Psi_n\}\leq\Psi_n\mathbb{E}\left[p_l|\nu\leq\Psi_n\right]\mathbb{P}\{\nu\leq\Psi_n\}\leq\Psi_n\mathbb{E}[p_l]=\Psi_nq_n,$$

and $0\leq p_l\leq 1$. (b) results from the fact that ν is exponentially-distributed. (c) follows from the facts that i) as we are considering the strong and moderate interference scenarios, it yields that $(n-1)\hat{\alpha}q_n=\Omega(1)$, or equivalently, $q_n=\Omega(\frac{1}{n})$, and ii) the term $(\Psi_n+1)e^{-\Psi_n}$ scales as $\frac{1}{n\log n}$ (due to the definition of Ψ_n) which is negligible with respect to the first term $q_n\Psi_n$. Combining (89) and (93) yields

$$\begin{aligned} \bar{R}_g &\lesssim \frac{Wnq_n\log n}{(n-1)\hat{\alpha}q_n+(1-\frac{\gamma}{2})\frac{N_0W}{M}} && (94)\\ &\lesssim \frac{W}{\hat{\alpha}}\log n && (95)\\ &\lesssim \frac{W}{\hat{\alpha}}\log K. && (96)\end{aligned}$$

In the case of weak interference, we have

$$\begin{aligned} \bar{R}_g &\leq nW\frac{\mathbb{E}[p_l\nu]}{\frac{N_0W}{M}} && (97)\\ &= \frac{Mn}{N_0}\mathbb{E}[p_l\nu]. && (98)\end{aligned}$$

Rewriting (92), we obtain

$$\mathbb{E}[p_l\nu] \;\leq\; q_n\Psi_n+(\Psi_n+1)e^{-\Psi_n}, \quad \forall\Psi_n>0. \tag{99}$$

Selecting $\Psi_n=\log(q_n^{-2})$ and defining $\varepsilon\triangleq nq_n$, we have

$$\bar{R}_g \;\lesssim\; \frac{2M\varepsilon}{N_0}\left(\log n-\log(\varepsilon^{-1})\right). \tag{100}$$

As in the weak interference scenario we have $\varepsilon = o(1)$, it follows from the above equation that $\bar{R}_g = o(W \log n)$ in this scenario. Comparing with (96), it follows that

$$\bar{R}_g \lesssim \frac{W}{\hat{\alpha}} \log K. \tag{101}$$

Lower-bound For the lower-bound, we consider the on-off power allocation scheme with $\tau_n = \log n - 2 \log \log n$. Also, assume that $M = 1$ (or equivalently, $n = K$). Noting $q_n = e^{-\tau_n}$, we obtain

$$\mathbb{E}[I_l] = (n-1)\hat{\alpha} q_n = \Theta(\log^2 n). \tag{102}$$

Therefore, using the result of Lemma 1, it is realized that with probability one $(n-1)\hat{\alpha} q_n (1-\epsilon) \leq I_l \leq (n-1)\hat{\alpha} q_n (1+\epsilon)$, for some $\epsilon = o(1)$. In other words, defining

$$\mathit{\Phi}(\nu) \triangleq \log \left(1 + \frac{p_l \nu}{(n-1)\hat{\alpha} q_n (1+\epsilon) + \frac{N_0 W}{M}} \right), \tag{103}$$

it follows that

$$\mathbb{P}\left\{ R_l(\mathbf{P}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)}) < \mathit{\Phi}(\nu) \right\} = o(1), \tag{104}$$

which implies that $R^*(\nu) \geq \mathit{\Phi}(\nu)$. As a result,

$$\begin{aligned}
\bar{R}_g &\geq nW \mathbb{E}[\mathit{\Phi}(\nu)] && (105)\\
&= nW \mathbb{E}\left[\log \left(1 + \frac{p_l \nu}{(n-1)\hat{\alpha} q_n (1+\epsilon) + \frac{N_0 W}{M}} \right) \right] && (106)\\
&\overset{(a)}{=} nW \int_{\tau_n}^{\infty} \log \left(1 + \frac{\nu}{(n-1)\hat{\alpha} q_n (1+\epsilon) + \frac{N_0 W}{M}} \right) e^{-\nu} d\nu && (107)\\
&\geq nW \int_{\tau_n}^{\Psi_n} \log \left(1 + \frac{\nu}{(n-1)\hat{\alpha} q_n (1+\epsilon) + \frac{N_0 W}{M}} \right) e^{-\nu} d\nu, && (108)
\end{aligned}$$

where $\Psi_n \triangleq \log n + 2 \log \log n$ and (a) follows from the on-off power allocation assumption. As $(n-1)\hat{\alpha} q_n (1+\epsilon) = \Theta(\log^2 n)$, it follows that $\frac{\nu}{(n-1)\hat{\alpha} q_n (1+\epsilon) + \frac{N_0 W}{M}} = o(1)$ in the interval $[\tau_n, \Psi_n]$, which implies that

$$\log \left(1 + \frac{\nu}{(n-1)\hat{\alpha} q_n (1+\epsilon) + \frac{N_0 W}{M}} \right) \sim \frac{\nu}{(n-1)\hat{\alpha} q_n (1+\epsilon) + \frac{N_0 W}{M}}, \tag{109}$$

in the interval of integration $[\tau_n, \Psi_n]$. Hence,

$$\begin{aligned}
\bar{R}_g &\gtrsim nW \int_{\tau_n}^{\Psi_n} \frac{\nu}{(n-1)\hat{\alpha} q_n (1+\epsilon) + \frac{N_0 W}{M}} e^{-\nu} d\nu && (110)\\
&= \frac{nW}{(n-1)\hat{\alpha} q_n (1+\epsilon) + \frac{N_0 W}{M}} \int_{\tau_n}^{\Psi_n} \nu e^{\nu} d\nu && (111)\\
&= \frac{nW}{(n-1)\hat{\alpha} q_n (1+\epsilon) + \frac{N_0 W}{M}} \left((\tau_n + 1) e^{-\tau_n} - (\Psi_n + 1) e^{-\Psi_n} \right) && (112)\\
&\overset{(a)}{\sim} \frac{nW \tau_n q_n}{(n-1)\hat{\alpha} q_n (1+\epsilon) + \frac{N_0 W}{M}} && (113)\\
&\sim \frac{W}{\hat{\alpha}} \log n && (114)\\
&= \frac{W}{\hat{\alpha}} \log K, && (115)
\end{aligned}$$

where (a) results from the facts that $(\Psi_n + 1)e^{-\Psi_n} \ll (\tau_n + 1)e^{-\tau_n}$ and $e^{-\tau_n} = q_n$. Combining the above equation with (101), the proof of Theorem 4 follows. ■

Remark 7- Similar to the proof steps of Theorem 1, it can be shown that the optimum value of M is equal to one. In fact, since the maximum guaranteed sum-rate of the network is achieved in the strong interference scenario in which the interference term scales as $n\hat{\alpha}q_n$ with probability one, it follows that the maximum network average sum-rate and the network guaranteed sum-rate are equal. Therefore, the optimum spectrum sharing for maximizing the network guaranteed sum-rate is the same as the one maximizing the average sum-rate of the network ($M = 1$).

V. CONCLUSION

In this paper, a distributed single-hop wireless network with K links was considered, where the links were partitioned into a fixed number (M) of clusters each operating in a subchannel with bandwidth $\frac{W}{M}$. The subchannels were assumed to be orthogonal to each other. A general shadow-fading model, described by parameters (α, ϖ), was considered where α denotes the probability of shadowing and ϖ ($\varpi \leq 1$) represents the average cross-link gains. The maximum achievable network throughput was studied in the asymptotic regime of $K \to \infty$. In the first part of the paper, the network throughput is defined as the *average sum-rate* of the network, which is shown to scale as $\Theta(\log K)$. Moreover, it was proved that in the strong interference scenario, the optimum power allocation strategy for each user was a threshold-based on-off scheme. In the second part, the network throughput is defined as the *guaranteed sum-rate*, when the outage probability approaches zero. In this scenario, it was demonstrated that the on-off power allocation scheme maximizes the network guaranteed sum-rate, which scales as $\frac{W}{\hat{\alpha}} \log K$. Moreover, the optimum spectrum sharing for maximizing the average sum-rate and guaranteed sum-rate is achieved at $M = 1$.

APPENDIX I

PROOF OF LEMMA 1

Let us define $\chi_k \triangleq \mathcal{L}_{ki} p_k$, where $\mathcal{L}_{ki}$ is independent of p_k, for $k \neq i$. Under a quasi-static Rayleigh fading channel model, it is concluded that χ_k's are independent and identically distributed (i.i.d.) random variables with

$$\begin{aligned}
\mathbb{E}\left[\chi_k\right] &= \mathbb{E}\left[\mathcal{L}_{ki} p_k\right] = \hat{\alpha} q_n, && \text{(A-1)}\\
\text{Var}\left[\chi_k\right] &= \mathbb{E}\left[\chi_k^2\right] - \mathbb{E}^2\left[\chi_k\right] && \text{(A-2)}\\
&\overset{(a)}{\leq} 2\alpha\kappa q_n - \left(\hat{\alpha} q_n\right)^2, && \text{(A-3)}
\end{aligned}$$

where $\mathbb{E}\left[h_{ki}^2\right] = 2$ and $\hat{\alpha} \triangleq \alpha\varpi$. Also, (a) follows from the fact that $p_k^2 \leq p_k$. Thus, $\mathbb{E}[p_k^2] \leq \mathbb{E}[p_k] = q_n$. The interference $I_i = \sum_{\substack{k\in\mathbb{C}_j\\ k\neq i}} \chi_k$ is a random variable with mean μ_n and variance ϑ_n^2, where

$$\begin{aligned}
\mu_n &\triangleq \mathbb{E}\left[I_i\right] = (n-1)\hat{\alpha} q_n, && \text{(A-4)}\\
\vartheta_n^2 &\triangleq \text{Var}\left[I_i\right] \leq (n-1)(2\alpha\kappa q_n - (\hat{\alpha} q_n)^2) \leq (n-1)(2\alpha\kappa q_n). && \text{(A-5)}
\end{aligned}$$

Using the *Central Limit Theorem* [37, p. 183], we obtain

$$\begin{aligned}
\mathbb{P}\{|I_i - \mu_n| < \psi_n\} &\approx 1 - Q\left(\frac{\psi_n}{\vartheta_n}\right) && \text{(A-6)}\\
&\overset{(a)}{\geq} 1 - e^{-\frac{\psi_n^2}{2\vartheta_n^2}}, && \text{(A-7)}
\end{aligned}$$

for all $\psi_n > 0$ such that $\psi_n = o\left(n^{\frac{1}{6}}\vartheta_n\right)$. In the above equation, the $Q(.)$ function is defined as $Q(x) \triangleq \frac{1}{\sqrt{2\pi}}\int_x^\infty e^{-u^2/2}du$, and (a) follows from the fact that $Q(x) \leq e^{-\frac{x^2}{2}}$, $\forall x > 0$. Selecting $\psi_n = (nq_n)^{\frac{1}{8}}\sqrt{2}\vartheta_n$, we obtain

$$\mathbb{P}\{|I_i - \mu_n| < \psi_n\} \geq 1 - e^{-(nq_n)^{\frac{1}{4}}}. \tag{A-8}$$

Therefore, defining $\varepsilon \triangleq \frac{\psi_n}{\mu_n} = O\left((nq_n)^{-\frac{3}{8}}\right)$, we have

$$\mathbb{P}\{\mu_n(1-\varepsilon) \leq I_i \leq \mu_n(1+\varepsilon)\} \geq 1 - e^{-(nq_n)^{\frac{1}{4}}}. \tag{A-9}$$

Noting that $nq_n \to \infty$, it follows that $I_i \sim \mu_n$, with probability one. Now, we show a stronger statement, which is, the contribution of the realizations in which $|I_i - \mu_n| > \psi_n$ in the network average sum-rate is negligible. For this purpose, we give a lower-bound and an upper-bound for the network average sum-rate and show that these bounds converge to each other in the strong interference regime, when $nq_n \to \infty$. A lower-bound denoted by $\bar{R}_{ave}^{(L)}$, can be given by

$$\begin{aligned}
\bar{R}_{ave}^{(L)} &\triangleq nW\mathbb{E}\left[\log\left(1 + \frac{\hat{p}_i h_{ii}}{I_i + \frac{N_0 W}{M}}\right)\middle| |I_i - \mu_n| < \psi_n\right]\mathbb{P}\{|I_i - \mu_n| < \psi_n\} && \text{(A-10)}\\
&\geq nW\mathbb{E}\left[\log\left(1 + \frac{\hat{p}_i h_{ii}}{\mu_n(1+\varepsilon) + \frac{N_0 W}{M}}\right)\right]\left[1 - e^{-(nq_n)^{\frac{1}{4}}}\right], && \text{(A-11)}
\end{aligned}$$

which scales as $\frac{W}{\hat{\alpha}} \log n$ (as shown in the proof of Theorem 1, by optimizing the power allocation function). An upper-bound for the network average sum-rate, denoted by $\bar{R}_{ave}^{(U)}$, can be given as

$$\begin{aligned} \bar{R}_{ave}^{(U)} &= nW\mathbb{E}\left[\log\left(1+\frac{\hat{p}_i h_{ii}}{I_i+\frac{N_0W}{M}}\right)\middle| |I_i-\mu_n|<\psi_n\right]\mathbb{P}\{|I_i-\mu_n|<\psi_n\}+ \\ &\quad nW\mathbb{E}\left[\log\left(1+\frac{\hat{p}_i h_{ii}}{I_i+\frac{N_0W}{M}}\right)\middle| |I_i-\mu_n|\geq\psi_n\right]\mathbb{P}\{|I_i-\mu_n|\geq\psi_n\} \quad \text{(A-12)} \\ &\leq \bar{R}_{ave}^{(L)} + nW\mathbb{E}\left[\log\left(1+\frac{\hat{p}_i h_{ii}}{\frac{N_0W}{M}}\right)\right]e^{-(nq_n)^{\frac{1}{4}}} \quad \text{(A-13)} \\ &\overset{(a)}{\leq} \bar{R}_{ave}^{(L)} + nW\mathbb{E}\left[\frac{\hat{p}_i h_{ii}}{\frac{N_0W}{M}}\right]e^{-(nq_n)^{\frac{1}{4}}} \quad \text{(A-14)} \\ &\overset{(b)}{=} \bar{R}_{ave}^{(L)} + WO(nq_n\log n)e^{-(nq_n)^{\frac{1}{4}}} \quad \text{(A-15)} \\ &\overset{(c)}{\sim} \bar{R}_{ave}^{(L)}. \quad \text{(A-16)} \end{aligned}$$

In the above equation, (a) follows from the fact that $\log(1+x) \leq x$, (b) comes from the facts that $\mathbb{E}\{p_i h_{ii}\} \lesssim q_n \log n$ (this is shown in the proof of Theorem 4) and $\frac{N_0W}{M}$ is fixed, and finally, (c) results from the fact that as $nq_n \to \infty$, $nq_n e^{-(nq_n)^{\frac{1}{4}}} \to 0$. The above equation implies that substituting I_i by its mean ($(n-1)\hat{\alpha}q_n$) does not affect the analysis of the network average sum-rate in the asymptotic case of $K \to \infty$.

APPENDIX II

PROOF OF LEMMA 2

Denoting $\mathbb{T}_j \triangleq \{l \in \mathbb{C}_j \mid h_{ll} > h_{Th}\}$, the cardinality of the set $\mathbb{T}_j$ is a binomial random variable with the mean $n\mathbb{P}\{h_{ll} > h_{Th}\}$. From (4), we have

$$\bar{R}_{ave} = \sum_{j=1}^{M} \mathbb{E}\left[\sum_{l\in\mathbb{C}_j} R_l(\hat{\mathbf{P}}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)})\right], \quad \text{(B-1)}$$

where

$$\mathbb{E}\left[\sum_{l\in\mathbb{C}_j} R_l(\hat{\mathbf{P}}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)})\right] = \mathbb{E}\left[\sum_{l\in\mathbb{T}_j} R_l(\hat{\mathbf{P}}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)})\right] + \mathbb{E}\left[\sum_{l\in\mathbb{T}_j^C} R_l(\hat{\mathbf{P}}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)})\right], \quad \text{(B-2)}$$

in which $\mathbb{T}_j^C$ denotes the complement of $\mathbb{T}_j$. Note that

$$\begin{aligned}
\mathbb{E}\left[\sum_{l\in\mathbb{T}_j} R_l(\hat{\mathbf{P}}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)})\right] &= n\frac{W}{M}\mathbb{E}\left[\log\left(1+\frac{h_{ll}\hat{p}_l}{I_l+\frac{N_0W}{M}}\right)\middle| h_{ll}>h_{Th}\right]\mathbb{P}\{h_{ll}>h_{Th}\} && \text{(B-3)}\\
&\leq n\frac{W}{M}\mathbb{E}\left[\log\left(1+\frac{h_{ll}}{\frac{N_0W}{M}}\right)\middle| h_{ll}>h_{Th}\right]\mathbb{P}\{h_{ll}>h_{Th}\} && \text{(B-4)}\\
&\overset{(a)}{\leq} \frac{n}{N_0}e^{-h_{Th}}\mathbb{E}\left[h_{ll}|h_{ll}>h_{Th}\right] && \text{(B-5)}\\
&= \frac{n}{N_0}e^{-h_{Th}}(1+h_{Th}), && \text{(B-6)}
\end{aligned}$$

where (a) follows from $\log(1+x)\leq x$, for $x>0$. It is observed that for $h_{Th}=c\log n$, where $c>1$, the right hand side of (B-6) tends to zero as $n\to\infty$. Thus,

$$\lim_{n\to\infty}\mathbb{E}\left[\sum_{l\in\mathbb{T}_j} R_l(\hat{\mathbf{P}}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)})\right]=0. \tag{B-7}$$

Consequently,

$$\lim_{n\to\infty}\sum_{j=1}^{M}\mathbb{E}\left[\sum_{l\in\mathbb{T}_j} R_l(\hat{\mathbf{P}}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)})\right]=0, \tag{B-8}$$

and this completes the proof of the lemma.

APPENDIX III
PROOF OF LEMMA 3

Using (32), we have

$$\begin{aligned}
\mathbb{E}[\Xi_i(\hat{p}_i,h_{ii})] &\approx \frac{W}{M\lambda}\mathbb{E}[h_{ii}\hat{p}_i]+n\frac{\alpha W\mu}{M\lambda'}\left(1-\frac{\varpi}{\lambda'}\mathbb{E}[\hat{p}_i]+\frac{2\kappa}{\lambda'^2}\mathbb{E}[\hat{p}_i^2]-\frac{6\eta}{\lambda'^3}\mathbb{E}[\hat{p}_i^3]\right)+\\
&\quad n(1-\alpha)\frac{W\mu}{M\lambda'} && \text{(C-1)}\\
&\overset{(a)}{=} \frac{W}{M\lambda}(1+\tau_n)q_n-\frac{n\hat{\alpha}W}{M\lambda'^2}(1+\tau_n)q_n^2+\frac{n\alpha W2\kappa}{M\lambda'^3}(1+\tau_n)q_n^2-\\
&\quad \frac{n\alpha W6\eta}{M\lambda'^4}(1+\tau_n)q_n^2+\frac{nW}{M\lambda'}(1+\tau_n)q_n && \text{(C-2)}\\
&\overset{(b)}{\approx} \frac{W}{M\hat{\alpha}}\left(1+\tau_n+\frac{\xi_1}{n^2}(1+\tau_n)e^{\tau_n}-\frac{\xi_2}{n^3}(1+\tau_n)e^{2\tau_n}\right), && \text{(C-3)}
\end{aligned}$$

where $\xi_1\triangleq\dfrac{2\kappa}{\varpi\hat{\alpha}}$ and $\xi_2\triangleq\dfrac{6\eta}{\varpi\hat{\alpha}^2}$. In the above equation, (a) follows from the fact that $\mathbb{E}[h_{ii}\hat{p}_i]=\mu=(1+\tau_n)q_n$, and (b) results from i) $\lambda=(n-1)\hat{\alpha}q_n+\frac{N_0W}{M}\approx n\hat{\alpha}q_n$ and $\lambda'\approx n\hat{\alpha}q_n$ incurred by the fact that $\lambda\gg 1$, and ii) $q_n=e^{-\tau_n}$. Since $n\hat{\alpha}q_n\to\infty$, it follows that the right hand side of (C-3) is a monotonically increasing function of τ_n, which attains its maximum when τ_n takes its maximum feasible value. The maximum feasible value of τ_n, denoted as $\hat{\tau}_n$, can be obtained as

$$n\hat{\alpha}e^{-\tau_n}\to\infty\Longrightarrow\hat{\tau}_n\sim\log n. \tag{C-4}$$

Thus, the maximum achievable value for $\mathbb{E}[\Xi_i(\hat{p}_i, h_{ii})]$ scales as $\dfrac{W}{M\hat{\alpha}} \log n$.

APPENDIX IV

PROOF OF LEMMA 4

$i)$ Using (8) and assuming that all users follow the on-off power allocation policy, $\mathbb{E}[u_i(\hat{p}_i, h_{ii})]$ can be expressed as

$$\mathbb{E}[u_i(\hat{p}_i, h_{ii})] = \sum_{l \in \mathbb{C}_j} \mathbb{E}\left[R_l(\hat{\mathbf{P}}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)})\right], \quad j = 1, ..., M, \tag{D-1}$$

where the expectation is computed with respect to h_{ll} and I_l. Noting that $q_n = \mathbb{P}\left\{h_{ll} > \tau_n\right\}$, we have

$$\begin{aligned} \mathbb{E}\left[R_l(\hat{\mathbf{P}}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)})\right] &= \mathbb{E}\left[R_l(\hat{\mathbf{P}}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)})\Big| h_{ll} > \tau_n\right]\mathbb{P}\left\{h_{ll} > \tau_n\right\} + \\ &\quad\ \mathbb{E}\left[R_l(\hat{\mathbf{P}}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)})\Big| h_{ll} \le \tau_n\right]\mathbb{P}\left\{h_{ll} \le \tau_n\right\} \\ &= q_n\mathbb{E}\left[R_l(\hat{\mathbf{P}}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)})\Big| h_{ll} > \tau_n\right] + (1 - q_n)\mathbb{E}\left[R_l(\hat{\mathbf{P}}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)})\Big| h_{ll} \le \tau_n\right]. \end{aligned} \tag{D-2}$$

Since for $h_{ll} \le \tau_n$, $\hat{p}_l = 0$, it is concluded that

$$\mathbb{E}\left[R_l(\hat{\mathbf{P}}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)})\right] = \frac{q_n W}{M}\mathbb{E}\left[\log\left(1 + \frac{h_{ll}}{I_l + \frac{N_0 W}{M}}\right)\Bigg| h_{ll} > \tau_n\right]. \tag{D-3}$$

For large values of K, we can apply Lemma 1 to obtain

$$\begin{aligned} \mathbb{E}\left[R_l(\hat{\mathbf{P}}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)})\right] &\approx \frac{q_n W}{M}\mathbb{E}\left[\log\left(1 + \frac{h_{ll}}{(n-1)\hat{\alpha}q_n + \frac{N_0 W}{M}}\right)\Bigg| h_{ll} > \tau_n\right] && \text{(D-4)} \\ &= \frac{q_n W}{M}\mathbb{E}\left[\log\left(1 + \frac{h_{ll}}{\lambda}\right)\Bigg| h_{ll} > \tau_n\right], && \text{(D-5)} \end{aligned}$$

where the expectation is computed with respect to h_{ll}. Using the Taylor series for $\log(1+x)$, (D-5) can be written as

$$\begin{aligned} \mathbb{E}\left[R_l(\hat{\mathbf{P}}^{(j)}, \boldsymbol{\mathcal{L}}_l^{(j)})\right] &\approx \frac{q_n W}{M}\sum_{k=1}^{\infty}\frac{(-1)^{k-1}}{k\lambda^k}\mathbb{E}\left[h_{ll}^k\middle| h_{ll} > \tau_n\right] && \text{(D-6)} \\ &\overset{(a)}{\approx} \frac{q_n W}{M}\sum_{k=1}^{\infty}\frac{(-1)^{k-1}}{k(n\hat{\alpha}q_n)^k}\mathbb{E}\left[h_{ll}^k\middle| h_{ll} > \tau_n\right] && \text{(D-7)} \\ &\overset{(b)}{\approx} \frac{q_n W}{M}\sum_{k=1}^{\infty}\frac{(-1)^{k-1}\tau_n^k}{k(n\hat{\alpha}q_n)^k} && \text{(D-8)} \\ &= \frac{q_n W}{M}\log\left(1 + \frac{\tau_n}{n\hat{\alpha}q_n}\right) && \text{(D-9)} \\ &\overset{(c)}{=} \frac{e^{-\tau_n}W}{M}\log\left(1 + \frac{\tau_n e^{\tau_n}}{n\hat{\alpha}}\right), && \text{(D-10)} \end{aligned}$$

where (a) follows from the fact that for large values of n, $\lambda \approx n\hat{\alpha}q_n$. Also, (b) results from the fact that under a Rayleigh fading channel model,

$$\mathbb{E}\left[h_{ll}\middle| h_{ll} > \tau_n\right] = 1 + \tau_n, \tag{D-11}$$

$$\mathbb{E}\left[h_{ll}^k \middle| h_{ll} > \tau_n\right] = \tau_n^k + k\mathbb{E}\left[h_{ll}^{k-1} \middle| h_{ll} > \tau_n\right]. \tag{D-12}$$

Since $\lambda \gg 1$, the term $\frac{\mathbb{E}\left[h_{ll}^{k-1}\middle|h_{ll}>\tau_n\right]}{\lambda^k} \ll \frac{\mathbb{E}\left[h_{ll}^{k-1}\middle|h_{ll}>\tau_n\right]}{\lambda^{k-1}}$, which implies that we can neglect this term and simply write $\mathbb{E}\left[h_{ll}^k\middle| h_{ll} > \tau_n\right] \approx \tau_n^k$. (c) results from $q_n = e^{-\tau_n}$. Thus, (D-1) can be simplified as

$$\mathbb{E}[u_i(\hat{p}_i, h_{ii})] \approx \frac{ne^{-\tau_n}W}{M} \log\left(1 + \frac{\tau_n e^{\tau_n}}{n\hat{\alpha}}\right). \tag{D-13}$$

In order to find the optimum threshold value:

$$\hat{\tau}_n = \arg \max_{\tau_n} \mathbb{E}[u_i(\hat{p}_i, h_{ii})], \tag{D-14}$$

we set the derivative of the right hand side of (D-13) with respect to τ_n to zero:

$$-e^{-\hat{\tau}_n} \log\left(1 + \frac{\hat{\tau}_n e^{\hat{\tau}_n}}{n\hat{\alpha}}\right) + \frac{1 + \hat{\tau}_n}{n\hat{\alpha} + \hat{\tau}_n e^{\hat{\tau}_n}} = 0, \tag{D-15}$$

which after some manipulations yields

$$\hat{\tau}_n = \log n - 2\log\log n + O(1). \tag{D-16}$$

$ii)$ Using (D-16), it is concluded that

$$\begin{aligned} q_n &= e^{-\tau_n} && \text{(D-17)} \\ &= \delta\frac{\log^2 n}{n}, && \text{(D-18)} \end{aligned}$$

where δ is a constant.

$iii)$ Using (D-16), we have

$$\frac{\hat{\tau}_n e^{\hat{\tau}_n}}{n\hat{\alpha}} = \Theta\left(\frac{1}{\log n}\right), \tag{D-19}$$

which implies that the right hand side of (D-13) can be written as

$$\text{RH (D-13)} \approx \frac{W\hat{\tau}_n}{M\hat{\alpha}}. \tag{D-20}$$

Thus, the maximum value for $\mathbb{E}[u_i(\hat{p}_i, h_{ii})]$ in (D-13) scales as $\frac{W}{M\hat{\alpha}}\log n$.

APPENDIX V

PROOF OF THEOREM 3

Let us define $\mathbb{A}_j$ as the set of active links in cluster j. The random variable m_j denotes the cardinality of the set $\mathbb{A}_j$. Noting that for $M = \Theta(K)$, $\lim_{K\to\infty} \frac{M}{K}$ is constant, it is concluded that n and $m_j \in [1, n]$ do not grow with K. To obtain the network average sum-rate, we assume that among M clusters, Γ clusters have $m_j = 1$ and the rest have $m_j > 1$. We first obtain an upper bound on the average sum-rate in each cluster when $m_j = 1$, $1 \leq j \leq M$. Clearly, since only one user in each cluster activates its transmitter, $I_i = 0$. Thus, by using (48), the maximum achievable average sum-rate of cluster $\mathbb{C}_j$ is computed as

$$\bar{R}_{ave}^{(j)} = \frac{W}{M}\mathbb{E}\left[\log\left(1 + \frac{M}{N_0 W}h_{\max}\right)\right], \tag{E-1}$$

where $h_{\max} \triangleq \max\ \{h_{ii}\}_{i\in\mathbb{C}_j}$ is a random variable. Since $\log x$ is a concave function of x, an upper bound of (E-1) is obtained through *Jensen's inequality*, $\mathbb{E}\left[\log x\right] \leq \log(\mathbb{E}\left[x\right])$, $x > 0$. Thus,

$$\bar{R}_{ave}^{(j)} \leq \frac{W}{M}\log\left(1 + \frac{M}{N_0 W}\mathbb{E}\left[h_{\max}\right]\right). \tag{E-2}$$

Under a Rayleigh fading channel model and noting that $\{h_{ii}\}$ is a set of i.i.d. random variables over $i \in \mathbb{C}_j$, we have

$$\begin{aligned} F_{h_{max}}(y) &= \mathbb{P}\{h_{\max} \leq y\}, \quad y > 0 && \text{(E-3)}\\ &= \prod_{i\in\mathbb{C}_j}\mathbb{P}\{h_{ii} \leq y\} && \text{(E-4)}\\ &= \left(1 - e^{-y}\right)^n, && \text{(E-5)}\end{aligned}$$

where $F_{h_{max}}(.)$ is the cumulative distribution function (CDF) of $h_{\max}$. Hence,

$$\mathbb{E}\left[h_{\max}\right] = \int_0^\infty nye^{-y}\left(1 - e^{-y}\right)^{n-1}dy. \tag{E-6}$$

Since $(1 - e^{-y})^{n-1} \leq 1$, we arrive at the following inequality

$$\mathbb{E}\left[h_{\max}\right] \leq \int_0^\infty nye^{-y}dy = n. \tag{E-7}$$

Consequently, the upper bound of (E-2) can be simplified as

$$\bar{R}_{ave}^{(j)} \leq \frac{W}{M}\log\left(1 + \frac{K}{N_0 W}\right). \tag{E-8}$$

For $m_j > 1$ and due to the shadowing effect with parameters (α, ϖ), the average sum-rate of cluster $\mathbb{C}_j$ can be written as

$$\bar{R}_{ave}^{(j)} = \sum_{i\in\mathbb{A}_j}\frac{W}{M}\mathbb{E}\left[\log\left(1 + \frac{h_{ii}}{\sum_{\substack{k\in\mathbb{A}_j\\ k\neq i}}u_k\beta_{ki}h_{ki} + \frac{N_0 W}{M}}\right)\right], \tag{E-9}$$

where u_k's are Bernoulli random variables with parameter α. Thus,

$$\begin{aligned} \bar{R}_{ave}^{(j)} &= \frac{W}{M}\sum_{i\in\mathbb{A}_j}\sum_{l=0}^{m_j-1}\binom{m_j-1}{l}\alpha^l(1-\alpha)^{m_j-1-l}\mathbb{E}\left[\log\left(1 + \frac{h_{ii}}{\Sigma_l + \frac{N_0 W}{M}}\right)\right] && \text{(E-10)}\\ &= \frac{W}{M}\sum_{i\in\mathbb{A}_j}(1-\alpha)^{m_j-1}\mathbb{E}\left[\log\left(1 + \frac{h_{ii}}{\frac{N_0 W}{M}}\right)\right] + \\ &\quad \frac{W}{M}\sum_{i\in\mathbb{A}_j}\sum_{l=1}^{m_j-1}\binom{m_j-1}{l}\alpha^l(1-\alpha)^{m_j-1-l}\mathbb{E}\left[\log\left(1 + \frac{h_{ii}}{\Sigma_l + \frac{N_0 W}{M}}\right)\right], && \text{(E-11)}\end{aligned}$$

where Σ_l is the sum of l i.i.d random variables $\{Z_i\}_{i=1}^{l}$, where $Z_i \triangleq \beta_{ki} h_{ki}$, $k \neq i$. For $m_j > 1$, Σ_l is greater than the interference term caused by one interfering link. Thus, an upper bound on the average sum-rate of cluster $\mathbb{C}_j$ is computed as

$$\begin{aligned}\bar{R}_{ave}^{(j)} \leq\ & \frac{W}{M} m_j (1-\alpha)^{m_j-1} \mathbb{E}\left[\log\left(1+\frac{Y}{\frac{N_0 W}{M}}\right)\right] + \\ & \frac{W}{M} \sum_{i \in \mathbb{A}_j} \sum_{l=1}^{m_j-1} \binom{m_j-1}{l} \alpha^l (1-\alpha)^{m_j-1-l} \mathbb{E}\left[\log\left(1+\frac{Y}{Z_i+\frac{N_0 W}{M}}\right)\right], \end{aligned} \tag{E-12}$$

where $Y \triangleq h_{\max} = \max\ \{h_{ii}\}_{i \in \mathbb{C}_j}$. According to binomial formula, we have

$$\sum_{l=1}^{m_j-1} \binom{m_j-1}{l} \alpha^l (1-\alpha)^{m_j-1-l} = 1-(1-\alpha)^{m_j-1}. \tag{E-13}$$

Thus,

$$\begin{aligned}\bar{R}_{ave}^{(j)} \leq\ & \frac{W}{M} m_j (1-\alpha)^{m_j-1} \mathbb{E}\left[\log\left(1+\frac{Y}{\frac{N_0 W}{M}}\right)\right] + \\ & \frac{W}{M} m_j \left(1-(1-\alpha)^{m_j-1}\right) \mathbb{E}\left[\log\left(1+\frac{Y}{\beta_{ki} h_{ki}+\frac{N_0 W}{M}}\right)\right]. \end{aligned} \tag{E-14}$$

We have

$$\mathbb{E}\left[\log\left(1+\frac{Y}{\beta_{ki} h_{ki}+\frac{N_0 W}{M}}\right)\right] \leq \mathbb{E}\left[\log\left(1+\frac{Y}{\beta_{\min} h_{ki}}\right)\right]. \tag{E-15}$$

Defining $Z \triangleq \beta_{\min} h_{ki}$ and $X \triangleq \frac{Y}{Z}$, the CDF of X can be evaluated as

$$\begin{aligned} F_X(x) &= \mathbb{P}\{X \leq x\}, \quad x > 0 && \text{(E-16)} \\ &= \mathbb{P}\{Y \leq Zx\} && \text{(E-17)} \\ &= \int_0^\infty \mathbb{P}\{Y \leq Zx | Z = z\} f_Z(z) dz && \text{(E-18)} \\ &= \int_0^\infty \left(1-e^{-zx}\right)^n \frac{1}{\beta_{\min}} e^{-\frac{z}{\beta_{\min}}} dz && \text{(E-19)} \\ &= \int_0^\infty \left(1-e^{-t\beta_{\min} x}\right)^n e^{-t} dt. && \text{(E-20)} \end{aligned}$$

Thus, the probability density function of X can be written as

$$\begin{aligned} f_X(x) &= \frac{dF_X(x)}{dx} && \text{(E-21)} \\ &= \beta_{\min} \int_0^\infty n t e^{-t(1+\beta_{\min} x)} \left(1-e^{-t\beta_{\min} x}\right)^{n-1} dt && \text{(E-22)} \\ &\leq \beta_{\min} \int_0^\infty n t e^{-t(1+\beta_{\min} x)} dt && \text{(E-23)} \\ &= \frac{n\beta_{\min}}{(1+\beta_{\min} x)^2}. && \text{(E-24)} \end{aligned}$$

Using the above equation, the right hand side of (E-15) can be upper-bounded as

$$\begin{aligned}
\mathbb{E}\left[\log\left(1+\frac{Y}{\beta_{\min}h_{ki}}\right)\right] &= \int_0^\infty f_X(x)\log(1+x)dx && \text{(E-25)}\\
&\leq n\beta_{\min}\int_0^\infty \frac{\log(1+x)}{(1+\beta_{\min}x)^2}dx && \text{(E-26)}\\
&= \frac{-n\log\beta_{\min}}{1-\beta_{\min}} && \text{(E-27)}\\
&= \Theta(1), && \text{(E-28)}
\end{aligned}$$

where the last line follows from the fact that $0 < \beta_{\min} \leq 1$. Substituting the above equation in (E-14) yields

$$\begin{aligned}
\bar{R}_{ave}^{(j)} &\leq \frac{W}{M}m_j(1-\alpha)^{m_j-1}\mathbb{E}\left[\log\left(1+\frac{Y}{\frac{N_0W}{M}}\right)\right]+\\
&\quad \frac{W}{M}m_j\left(1-(1-\alpha)^{m_j-1}\right)\Theta(1) && \text{(E-29)}\\
&\overset{(a)}{\leq} \frac{W}{M}m_j(1-\alpha)^{m_j-1}\log\left(1+\frac{K}{N_0W}\right)+\Theta\left(\frac{W}{M}\right) && \text{(E-30)}\\
&= \frac{W}{M}m_j(1-\alpha)^{m_j-1}\log\left(1+\frac{K}{N_0W}\right)\left[1+o(1)\right], && \text{(E-31)}
\end{aligned}$$

where (a) follows from (E-8) and the fact that $m_j \in \{2,...,n\}$ does not scale with K.

Let us assume that among M clusters, Γ clusters have $m_j = 1$ and for the $M-\Gamma$ of the rest, the number of active links in each cluster is greater than one. By using (E-8) and (E-29), an upper bound on the network average sum-rate is obtained as

$$\begin{aligned}
\bar{R}_{ave} &\leq \frac{\Gamma W}{M}\log\left(1+\frac{K}{N_0W}\right)+\\
&\quad (M-\Gamma)\frac{W}{M}m_j(1-\alpha)^{m_j-1}\log\left(1+\frac{K}{N_0W}\right)\left[1+o(1)\right]. && \text{(E-32)}
\end{aligned}$$

To compare this upper-bounded with the computed network average sum-rate in the case of $M=1$, we note that as $\varpi \leq 1$ and $\alpha < 1$, we have $\hat{\alpha} < 1$ and consequently,

$$\frac{\Gamma W}{M}\log\left(1+\frac{K}{N_0W}\right) < \frac{\Gamma W}{M\hat{\alpha}}\log\left(1+\frac{K}{N_0W}\right). \qquad \text{(E-33)}$$

To prove that the maximum network average sum-rate obtained in (E-32) is less than that value obtained for $M=1$ from (18), it is sufficient to show

$$(M-\Gamma)\frac{W}{M}m_j(1-\alpha)^{m_j-1}\log\left(1+\frac{K}{N_0W}\right) < (M-\Gamma)\frac{W}{M\hat{\alpha}}\log\left(1+\frac{K}{N_0W}\right), \qquad \text{(E-34)}$$

or

$$m_j(1-\alpha)^{m_j-1} < \frac{1}{\hat{\alpha}}. \qquad \text{(E-35)}$$

Since $\hat{\alpha} \leq \alpha$, it is sufficient to show that $m_j(1-\alpha)^{m_j-1} < \frac{1}{\alpha}$. Defining $\Lambda(\alpha) = \alpha m_j(1-\alpha)^{m_j-1}$, we have

$$\frac{\partial \Lambda(\alpha)}{\partial \alpha} = m_j(1-\alpha)^{m_j-2}(1-\alpha m_j). \tag{E-36}$$

Thus, the extremum points of $\Lambda(\alpha)$ are located at $\alpha = 1$ and $\alpha = \frac{1}{m_j}$, where $m_j \in \{2, ..., n\}$. It is observed that

$$\Lambda(1) = 0 < 1, \tag{E-37}$$

and

$$\Lambda\left(\frac{1}{m_j}\right) = \left(\frac{m_j - 1}{m_j}\right)^{m_j-1} < 1. \tag{E-38}$$

Since $\Lambda(\alpha) < 1$, we conclude (E-34), which implies that the maximum average sum-rate of the network for $M = \Theta(K)$ is less than that of $M = 1$. Knowing the fact that for $M = o(K)$, similar to the result of Theorem 1, one can show that the maximum average sum-rate of the network is achieved at $M = 1$, it is concluded that using the on-off allocation scheme, the maximum average sum-rate of the network is achieved at $M = 1$, for all values of $1 \leq M \leq K$.

APPENDIX VI
PROOF OF REMARK 4

Using (3) and (4) and for every value of $1 \leq M \leq K$ and $\alpha = 0$, the average sum-rate of the network is simplified as

$$\bar{R}_{ave} = \sum_{j=1}^{M} \sum_{i \in \mathbb{C}_j} \mathbb{E}\left[\frac{W}{M} \log\left(1 + \frac{h_{ii}}{\frac{N_0 W}{M}}\right)\right], \tag{F-1}$$

where the expectation is computed with respect to h_{ii}. Under a Rayleigh fading channel condition and using the fact that $n = \frac{K}{M}$, (F-1) can be written as

$$\begin{aligned}
\bar{R}_{ave} &= nW \int_0^\infty e^{-x} \log\left(1 + \frac{M}{N_0 W} x\right) dx && \text{(F-2)}\\
&= \frac{KW}{M} e^{\frac{N_0 W}{M}} \mathrm{E}_1\left(\frac{N_0 W}{M}\right) && \text{(F-3)}\\
&= \frac{KW}{M} e^{\frac{N_0 W}{M}} \int_1^\infty \frac{e^{-t\frac{N_0 W}{M}}}{t} dt, && \text{(F-4)}
\end{aligned}$$

where $\mathrm{E}_1(x) = -\mathrm{Ei}(-x) = \int_1^\infty \frac{e^{-tx}}{t} dt$, $x > 0$. Taking the first-order derivative of (F-4) in terms of M yields,

$$\frac{\partial \bar{R}_{ave}}{\partial M} = -\frac{KW}{M^2} e^{\frac{N_0 W}{M}} \left(1 + \frac{N_0 W}{M}\right) \mathrm{E}_1\left(\frac{N_0 W}{M}\right) + \frac{KW}{M^2}. \tag{F-5}$$

Since for every value of $N_0 W$, $\dfrac{\partial \bar{R}_{ave}}{\partial M}$ is negative, it is concluded that the network average sum-rate is a monotonically decreasing function of M. Consequently, the maximum average sum-rate of the network for $\alpha = 0$ and every value of $1 \leq M \leq K$ is achieved at $M = 1$.

APPENDIX VII

PROOF OF REMARK 5

From (3) and (4), the average sum-rate of the network is given by

$$\begin{aligned}\bar{R}_{ave} &= \mathbb{E}\left[\sum_{i=1}^{K} R_i(\hat{\mathbf{P}}^{(j)}, \boldsymbol{\mathcal{L}}_i^{(j)})\right] && \text{(G-1)}\\ &= \frac{W}{K}\sum_{i=1}^{K}\mathbb{E}\left[\log\left(1+\frac{h_{ii}}{\frac{N_0 W}{K}}\right)\right], && \text{(G-2)}\end{aligned}$$

where the expectation is computed with respect to h_{ii}. Under a Rayleigh fading channel condition, we have

$$\begin{aligned}\bar{R}_{ave} &= W\int_0^{\infty} e^{-x}\log\left(1+\frac{K}{N_0 W}x\right)dx && \text{(G-3)}\\ &= We^{\frac{N_0 W}{K}}\mathrm{E}_1\left(\frac{N_0 W}{K}\right). && \text{(G-4)}\end{aligned}$$

To simplify (G-4), we use the following series representation for $\mathrm{E}_1(x)$,

$$\mathrm{E}_1(x) = -\boldsymbol{\gamma} + \log\left(\frac{1}{x}\right) + \sum_{s=1}^{\infty}\frac{(-1)^{s+1}x^s}{s.s!}, \quad x > 0, \tag{G-5}$$

where $\boldsymbol{\gamma}$ is Euler's constant and is defined by the limit [34]

$$\boldsymbol{\gamma} \triangleq \lim_{s\to\infty}\left(\sum_{k=1}^{s}\frac{1}{k} - \log s\right) = 0.577215665...$$

Thus, (G-4) can be simplified as

$$\bar{R}_{ave} = We^{\frac{N_0 W}{K}}\left(-\boldsymbol{\gamma} + \log\left(\frac{K}{N_0 W}\right) + \sum_{s=1}^{\infty}\frac{(-1)^{s+1}}{s.s!}\left(\frac{N_0 W}{K}\right)^s\right). \tag{G-6}$$

In the asymptotic case of $K \to \infty$,

$$e^{\frac{N_0 W}{K}} \approx 1, \tag{G-7}$$

and

$$\sum_{s=1}^{\infty}\frac{(-1)^{s+1}}{s.s!}\left(\frac{N_0 W}{K}\right)^s \approx 0. \tag{G-8}$$

Consequently, the network average sum-rate for $M = K$ is asymptotically obtained by

$$\bar{R}_{ave} \approx W(\log K - \log N_0 W - \boldsymbol{\gamma}). \tag{G-9}$$
